#### Abstract

Several new *Arthrinium* specimens were collected from various locations in Mediterranean and temperate Europe. A collection of the type species, *A. caricicola*, was obtained from dead leaves of *Carex ericetorum* in Berlin. Sequences of four genetic markers, ITS, 28S rDNA, tef1 and tub2 were produced from almost all collections and analyzed with those available in public databases. Results are employed to support six new species: *A. balearicum, A. descalsii, A. esporlense, A. ibericum, A. italicum* and *A. piptatheri*. The type species, *A. caricicola*, is related to other species occurring on *Carex* sp.; these might represent an independent lineage from *Apiospora* and the remaining species of *Arthrinium*. Finally, the sexual morph of *A. marii* is described and illustrated for the first time.

#### Keywords

Apiosporaceae, Ascomycota, Sordariomycetes, Xylariales, ITS, 28S rDNA, tef1, tub2

## Introduction

The genus *Arthrinium* Kunze (Apiosporaceae, Sordariomycetes) differs from other anamorphic genera because of the presence of basauxic conidiophores, which arise from structures called conidiophore mother cells (Schmidt and Kunze 1817; Hughes 1953;

Copyright Ángel Pintos et al. This is an open access article distributed under the terms of the Creative Commons Attribution License (CC BY 4.0), which permits unrestricted use, distribution, and reproduction in any medium, provided the original author and source are credited.

Minter 1985). This infrequent type of conidiogenesis can be found also in *Cordella* Speg., *Dictyoarthrinium* S. Hughes, *Pteroconium* Sacc. ex Grove, and *Spegazzinia* Sacc. (Ellis 1971), but *Pteroconium* and *Cordella* are now considered synonyms of *Athrinium* (Seifert et al. 2011; Crous and Groenewald 2013). *Apiospora* Sacc., the sexual state of *Arthrinium*, is also considered a synonym based on the one fungus-one name policy (Hawksworth et al. 2011; Crous and Groenewald 2013), and *Nigrospora* Zimm. is thought to be the closest relative (Wang et al. 2017).

There are about 80 valid species names of Arthrinium. The most significant contributions to species diversity of Arthrinium before the DNA-era were those of Schmidt and Kunze (1817), Kunze and Schmidt (1823), Fuckel (1870, 1874), Ellis (1963, 1965, 1971, 1976), and Larrondo and Calvo (1990, 1992). Genetic evidence allowed to confirm some of these taxa and propose multiple new species, e.g. Crous and Groenewald (2013), Singh et al. (2013), Dai et al. (2016, 2017), Jiang et al. (2018), and Wang et al. (2018). Smith et al. (2003) produced the first genetic data (18S and 28S rDNA) of A. phaeospermum (Corda) M.B. Ellis, supporting that this genus, as well as Apiospora, represent a separate family within Xylariales. This was later confirmed by Spatafora et al. (2006) and Zhang et al. (2006) who added new information from gene-coding DNA markers (18S and 28S rDNA, tef1, rpb2). Singh et al. (2013) published a ITS rDNA phylogeny including several type sequences obtained by Ogawa et al. (unpublished), such as those of A. marii Larrondo & Calvo, A. hispanicum Larrondo & Calvo, A. mediterranei Larrondo & Calvo, A. serenense Larrondo & Calvo, and A. phaeospermum, and introduced the new species A. rasikravindrae Shiv M. Singh, L.S. Yadav, P.N. Singh, Rah. Sharma & S.K. Singh (as rasikravindrii). Soon afterwards, Crous and Groenewald (2013) published a comprehensive re-evaluation of Arthrinium based on multigenic data, introducing eight new species and providing genetic data from several type strains of other taxa. They formally proposed the synonymy between Arthrinium and Apiospora, giving priority to Arthrinium, but provided no data of the type species, A. caricicola Kunze & J.C. Schmidt. Sharma et al. (2014) published the new species A. jatrophae R. Sharma, G. Kulk. & Shouche and built a phylogenetic tree based on rDNA that showed three main clades: one formed by A. urticae M.B. Ellis, a second including A. puccinioides Kunze & J.C. Schmidt and A. japonicum Pollack & C.R. Benj., and a third including the remaining known species of Arthrinium and Apiospora. Multigenic data of the first two clades was first obtained by Ogawa et al. (unpublished), and also Crous and Groenewald (2013), although they did not include these data in their phylogenetic analyses. Some new species of Arthrinium were described in the next years (Crous et al. 2015; Senanayake et al. 2015; Hyde et al. 2016; Dai et al. 2016, 2017; Wang et al. 2018; Jiang et al. 2018), and the multilocus phylogenetic analysis revealed that the sister clade of Arthrinium was Nigrospora in Apiosporaceae (Wang et al. 2017).

Morphological features traditionally employed to discriminate between species of *Arthrinium* include conidial shape, conidiophores, presence or absence of sterile cells and the presence of setae. Two great groups of species can be discriminated: 1) those with irregularly shaped conidia (including the type species *A. cariciola* and several oth-

ers mainly associated with *Carex* spp. (Cyperaceae, Poales), such as *A. austriacum* Petr., *A. fuckelii* Gjaerum, *A. globosum* Koskela, *A. japonicum*, *A. kamtschaticum* Tranzschel & Woron., *A. morthieri* Fuckel, *A. muelleri* M.B. Ellis, *A. naviculare* Rostr., *A. puccinioides* and *A. sporophleum* Kunze), and 2) the remaining species with globose to ellipsoid conidia, mainly associated with other plants in the Poales (Cyperaceae, Poaceae, Restionaceae), e.g. *A. pterospermum* (Cooke & Massee) Arx, *A. phragmitis* Crous, *A. sacchari* (Speg.) M.B. Ellis, *A. saccharicola* F. Stevens, *A. kogelbergense* Crous, and *A. hysterinum* (Sacc.) P.M. Kirk, or even a wider diversity of potential hosts, such as *A. arundinis* (Corda) Dyko & B. Sutton, *A. phaeospermum*, *A. rasikravindrae* and *A. malaysianum* Crous.

Spatafora et al. (2006) and Zhang et al. (2006) were the first to obtain genetic data from the type species of Apiospora, Ap. montagnei Sacc. (CBS 212.30, AFTOL-ID 951) and suggested that it belongs in a distinct family within Xylariales. Sequences of a few other species of Apiospora are also available, including Ap. sinensis K.D. Hyde, J. Fröhl. & Joanne E. Taylor (HKUCC 3143 in Smith et al. 2003), Ap. setosa Samuels, McKenzie & D.E. Buchanan (ICMP 6888 /ATCC 58184 ex type PDD 41017 in Huhndorf et al. 2004), and Ap. tintinnabula Samuels, McKenzie & D.E. Buchanan (ICMP 6889-96 ex type PDD 41022 in Jaklitsch and Voglmayr 2012). Jaklitsch and Voglmayr (2012) produced a 28S rDNA phylogeny where the type species Ap. montagnei seemed not significantly different from Ap. sinensis but distinct from the other species sequenced. In addition, some Apiospora sexual morphs have been biologically linked with putatively prioritary Arthrinium taxa: A. hysterinum = Ap. bambusae (Turconi) Sivan. (Sivanesan 1983; Kirk 1986; Réblová et al. 2016), A. arundinis = Ap. montagnei (Hyde et al. 1998), and A. sinense = Ap. sinense (Réblová et al. 2016). However, none of these putative synonymies has been confirmed with genetic data, as some type collections are missing or too old for standard DNA analysis.

The aim of the present study was to study new *Arthrinium* samples found in temperate and southern Europe, including one specimen of *A. caricicola* and several putatively new species, and compare them morphologically and genetically with existing taxa. In some cases, e.g. *Ap. tintinnabula*, type collections were loaned and additional sequences obtained to delimit the genetic boundaries of some species.

#### Materials and methods

#### Pure culture isolation

During the surveys conducted in 2017 and 2018, 34 fresh specimens were collected from various plant hosts in Germany, Italy, Portugal and Spain. To isolate the sexual morph, ascomata were removed from the stromata using a sterile razor blade, transferred to a water droplet mounted on a microscope slide, torn apart with forceps to release the ascospores from asci, and pipetted on a 2% malt extract agar (MEA) plate supplemented with 200 mg/L penicillin G and streptomycin sulphate. Germinated ascospores were then transferred to MEA 2% plates, which were sealed with plastic film and incubated at room temperature. To isolate the asexual morph, plate cultures were superficially scrapped with a needle to dislodge conidia that were transferred to a drop of water. The suspension was then picked up with a syringe, and small droplets sown on a MEA 2% plate supplemented with 200 mg/L penicillin G and streptomycin sulphate. The germinated conidia were then transferred to 2% MEA plates, which were sealed with laboratory film and incubated at room temperature. Cultures were deposited at CBS-KNAW Fungal Biodiversity Centre, Utrecht, The Netherlands (CBS).

#### Morphological observations

Hand sections of stromata or conidiomata were made using a razor blade and mounted in water on a microscope slide. Observations were made with a Zeiss Axioscop microscope using differential interference contrast (DIC), images were taken with a FLIR camera with A. Coloma open source software. Measurements were taken with FIJI ImajeJ software, reported with maximum and minimum values in parentheses, and the range representing the mean plus and minus the standard deviation, followed by the number of measurements in parentheses. For certain images of conidiophores, the image stacking software Zerene Stacker v. 1.04 (Zerene Systems LLC, Richland, WA, USA) was used. Morphological descriptions were based on cultures sporulating on 2% MEA medium at room temperature. The original specimens were deposited at the fungarium of the Real Jardin Botanico de Madrid (MA-Fungi).

#### DNA isolation, amplification and phylogenetic analyses

Total DNA was extracted from dry specimens employing a modified protocol based on Murray and Thompson (1980). PCR amplification was performed with the primers ITS1F and ITS4 (White et al. 1990; Gardes and Bruns 1993) for ITS region, while LR0R and LR5 (Vilgalys and Hester 1990; Cubeta et al. 1991) were used to amplify the 28S rDNA region, T1, Bt2a, and Bt2b (Glass and Donaldson 1995; O'Donnell and Cigelnik 1997) for the  $\beta$ -tubulin gene (tub2), and EF1-728F, EF1-983F and EF1-1567R (Rehner and Buckley 2005) for the translation elongation factor 1a (tef1) gene. PCR reactions were performed under a program consisting of a hot start at 95 °C for 5 min, followed by 35 cycles at 94 °C, 54 °C and 72 °C (45, 30 and 45 s respectively) and a final 72 °C step 10 min. PCR products were checked in 1% agarose gels, and positive reactions were sequenced with one or both PCR primers. Chromatograms were checked searching for putative reading errors, and these were corrected.

BLAST (Altschul et al. 1990) was used to select the most closely related sequences from INSDC public databases. Sequences came mainly from Crous and Groenewald (2013), Singh et al. (2013), Sharma et al. (2014), Crous et al. (2015), Senanayake et al. (2015), Dai et al. (2016, 2017), Hyde et al. (2016), Réblová et al. (2016), Jiang et

al. (2018), and Wang et al. (2018), as well as Ogawa et al. (unpublished). Two distinct alignments were built in MEGA 5.0 (Tamura et al. 2011) and aligned with Clustal W with manual corrections: 1) a multigenic alignment including ITS, 28S rDNA, tub2 and tef1 data (without introns) from all Apiosporaceae and related families, and 2) a second alignment built with the same DNA markers (with introns) including only species related with A. sacchari (/saccharii clade). Introns were removed from tef1 and tub2, and GBlocks (Castresana 2000) was employed to remove 201 ambiguously aligned sites from ITS rDNA in the Apiosporaceae alignment, but not in the alignment of the /sacchari clade, in order to resolve this complex with all the phylogenetic signal available. The final alignment of the Apiosporaceae included five partitions with 217/461 (ITS rDNA), 229/846 (28S rDNA), 78/252 (tub2), 43/147 (tef1 EF1-728F to EF1-983F), and 76/413 (tef1 EF1-983F to EF1-1567R) variable sites, while the final alignment of the /sacchari clade had 35/535 (ITS rDNA), 18/837 (28S rDNA), 99/719 (tub2), 68/429 (tef1 EF1-728F to EF1-983F), and 4/407 (tef1 EF1-983F to EF1-1567R) variable sites. The aligned loci were loaded in PAUP\* 4.0b10 (Swofford 2001) and subjected to MrModeltest 2.3 (Nylander 2004). Model GTR+G+I was selected and implemented in all partitions in MrBayes 3.2.6 (Ronquist and Huelsenbeck 2003), where a Bayesian analysis was performed (data partitioned, two simultaneous runs, six chains, temperature set to 0.2, sampling every 100th generation) until convergence parameters were met after about 3.43M generations (Apiosporaceae) or 0.9M (/sacharii clade), standard deviation having fell below 0.01. Finally, a full search for the best-scoring maximum likelihood tree was performed in RAxML (Stamatakis 2006) using the standard search algorithm (data partitioned, GTRMIX model, 2000 bootstrap replications). Significance threshold was set above 0.95 for posterior probability (PP) and 70% bootstrap proportions (BP).

#### Results

#### Phylogeny

The analysis of ITS, 28S rDNA, tef1 and tub2 data from the entire family Apiosporaceae (Fig. 1) produced a phylogeny with two main significantly supported clades: 1) composed of *A. puccinioides*, *A. japonicum* and newly sequenced specimens matching the species *A. cariciola*, *A. curvatum* var. *minus*, and *A. sporophleum*, and 2) a second clade containing all other sequences of *Arthrinium* and *Apiospora*. Among the other specimens analyzed, some matched the genetic concept of *A. hysterinum*, *A. phragmitis*, *A. arundinis*, *A. rasikravindrae*, or *A. marii*. Five new lineages were also found, which are formally proposed as new taxa below.

The analysis of ITS, 28S rDNA, tef1 and tub2 of the species around *A. sacchari* (/sacchari clade) (Fig. 2) showed that the clade of *A. marii* contains the types of *A. hispanicum* and *A. mediterranei*, but receives low overall support, maybe because of the incomplete data from these two species. Samples CBS 113535 and CBS 114803 were identified as *A. marii* too, but seem to represent an independent lineage.

Bold names represent samples sequenced in the present study.

#### Taxonomy

#### Arthrinium balearicum Pintos & P. Alvarado, sp. nov.

MycoBank: MB 828866 Fig. 3

Etymology. Refers to the Balearic Islands (Spain), where the holotype was found.

**Diagnosis.** Sexual morph: *Stromata* forming black, linear, confluent raised areas on host surface, with the longer axis broken at the apex,  $(500-)600-1500(-2000) \ \mu m \times (200-)320-450(-500) \ \mu m (n = 20)$ . *Ascomata* globose to subglobose, with flattened base, blackish brown,  $(120-) \ 140-180 \ (-200) \ \mu m$  in diameter (n = 30). *Peridium* 8–15  $\mu m$  thick, consisting of 4–5 layers of cells arranged in *textura angularis*, externally dark brown, hyaline in the inner part. *Ostiole* single, central, 30–60  $\mu m$  in diameter, with a periphysate channel 20–30  $\mu m$  long. *Peryphises* broad, colourless. *Hamathecium* composed of dense hypha-like, broad septate paraphyses, deliquescing early, 4–6  $\mu m$  thick. *Asci* 8-spored, unitunicate, clavate, broadly cylindrical, with an inconspicuous pedicel, rounded apex,

**Figure 3.** *A. balearicum* **A** stromata on host; **B** asci **C**–**F** ascospores **G** colony on MEA. Scale bars: 200 μm (**A**); 20 μm (**B**); 5 μm (**C**–**F**).

thin-walled, without an apical apparatus, measuring  $(77-)80-98(-105) \times (14-)15-19(-21) \mu m$  (n = 22). *Ascospores* 1–3-seriate, hyaline, apiospore smooth-walled, fusiform, elliptical, reniform, straight or curved, bicellular, wider at the center of the longest cell, measuring  $(23-)26-30(-32) \times (7-)9-10(-12) \mu m$  (n = 35), basal cell 3–6  $\mu m$  long, sometimes containing a droplet. Asexual morph: not observed. Culture characteristics: colonies flat spreading on MEA 2%, with moderate aerial mycelium, reverse withish.

**Type.** Spain: Balearic Islands: Mallorca, Llucmajor, on undetermined Poaceae, 24 Jan. 2018, *A. Pintos* (MA-Fungi 91723 holotype, AP24118 isotype, CBS 145129 ex-type culture).

**Notes.** Arthrinium balearicum is related with A. descalsii, but has some genetic differences with this species having only 93% (482/518 bp) of its ITS rDNA, 99% (821/823 bp) of 28S rDNA, 97% (688/707 bp) of tef1, and 98% (406/413 bp) of tub2 similar. It is also phylogenetically close to A. phragmitis, a species with a similar ascospore size,  $(23-)26-30(-32) \times (7-)9-10(-12) \mu m$  in A. balearicum and  $(22-)23-28(-30) \mu m \times (6-)7-9(-10) \mu m$  in A. phragmitis. Unfortunately, the asexual morph of A. balearicum could not be studied to compare it with that of A. phragmitis.

# Arthrinium caricicola Kunze & J.C. Schmidt, Mykologische Hefte (Leipzig) 1: 9 (1817)

Fig. 4

**Description.** Asexual morph: *colonies* on the host punctiform, pulvinate, 140–400  $\mu$ m in diameter, blackish brown. *Mycelium* formed by hyaline smooth, branched hyphae, 2–5  $\mu$ m in diameter. *Conidiophore mother cells* arising from a superficial or erumpent mycelial mat, subspherical to lageniform in shape, hyaline with brown pigments at the base, measuring (4–)5–7(–8) × (8–)9–11(–12)  $\mu$ m (*n* = 45). *Conidiophores* erect or ascending, simple, straight or flexuous, cylindrical, smooth-walled, colourless excepting for the thick, brown to dark brown, transversal septa, 15–100 × 3–5  $\mu$ m (*n* = 50). *Conidia* fusiform or broadly spindle-shaped, smooth-walled, broader at the mid-

**Figure 4.** *A. caricicola* **A** colony on host **B** colony on MEA **C** conidiophore mother cell **D**, **E** conidiophore mother cell, conidiophore bearing conidia, conidia **F**–**H** conidia **I** conidia with scar **J** lobate sterile cells. Scale bars: 200  $\mu$ m (**A**); 5  $\mu$ m (**C**–**I**); 10  $\mu$ m (**J**). **K** *A. caricicola* syntype, colonies on host; **L**, **M** conidia.

27

dle, tapering towards the narrowly rounded ends, dark brown with a hyaline rim,  $(37-)44-51(-55) \mu m$  in frontal view,  $(8-)9-11(-12) \mu m$  in side view (n = 50). Sterile cells smaller,  $15-19 \times 10-13 \mu m$ , and paler than conidia, bicuspidate or irregularly lobed. Culture characteristics: flat colonies spreading on MEA 2%, with moderately abundant, white cottony aerial mycelium, reverse whitish too, circular in shape with irregular edge.

**Notes.** The conidia of *A. caricicola* and *A. japonicum* have a similar fusiform shape and length, but differ in width  $((8-)9-11(-12) \mu m vs 12-16(-20) \mu m)$ . Conidia of *A. mytilimorphum* have also a similar shape, but turns out shorter and thinner  $(20-30 \times 6-8.5 \mu m)$ . The morphological characters of the syntype of *A. caricicola* deposited by Fries in the Herbarium of Uppsala University as Fung. Scleromyc. Suecici, fully match the specimen collected in this study. The closely related species *A. sporophleum* has very different lemon-shaped conidia, while those of *A. curvatum* var. *minus* are curved, and those of *A. puccinioides* are polygonal.

**Specimens examined.** Germany: *Brandenburg*: south of Liberose, on dead leaves of *Carex ericetorum*, 14 May 2018, *R. Jarling* (MA-Fungi 91725).

# Arthrinium curvatum var. minus M.B. Ellis, Trans. Brit. Mycol. Soc. 34: 501 (1951)

Fig. 5

*Physalospora scirpi* Arx, Gen. Fungi Sporul. Cult. (Lehr): 116 (1970). *Pseudoguignardia scirpi* Gutner, Mater. Mikol. Fitopat. Ross. 6(1): 311 (1927).

**Description.** Asexual morph: *Colonies* are compact, round, dark to black, 80–320 in diameter. *Mycelium* is composed of hyaline to pale brown smooth hyphae 2–7 µm in diameter. *Conidiophore mother cells* spherical to lageniform, hyaline with brown pigments at the base, measuring  $(4-)5-7(-8) \times (4-)5-6(-7) \mu m$  (n = 30). *Conidiophores* cylindrical unbranched, straight or flexuous, hyaline and smooth walled, with a single brown transversal septa, measuring  $30-100 \times 2-4 \mu m$ . (n = 30). *Conidiogenous cells* cylindrical  $1-1.5 \times 1-1.5 \mu m$  (n = 20). *Conidia* borne along the sides of conidiophores, curved, rounded at the ends, brown, with a hyaline germ slit and a clearly visible scar, (8-)9–10(–11) µm long in frontal view, (5-)6–7(–8) µm in side view (n = 30). *Sterile cells* rounded, paler than conidia. *Culture characteristics* flat colonies spreading on MEA 2% with moderate aerial mycelium, reverse withish.

**Notes.** Arthrinium curvatum var. minus can be confused with A. curvatum var. curvatum, but conidia of var. minus measure  $(8-)9-10(-11) \times (5-)6-7(-8) \mu m$ , while those of A. curvatum var. curvatum measure  $11-15 \times 6-8 \mu m$ . Gutner (1927) described Pseudoguignardia scirpi, a sexual morph of A. curvatum, later combined as Physalospora scirpi (Arx 1970). Arthrinium curvatum var. minus is closely related with A. sporophleum (with lemon-shaped conidia) and A. japonicum (with larger fusiform conidia) and to a lesser extent also with A. caricicola (with larger fusiform conidia) and A. puccinioides (with polygonal conidia). Ellis et al. (1951) described A. curvatum var. minus, a taxon

**Figure 5.** *A. curvatum* var. *minus* **A** colony on host **B** conidiophore mother cell **C**, **D** conidiophore mother cell, conidiophore bearing conidia **E**, **F** curved conidia **G** colony on MEA. Scale bars: 200  $\mu$ m (**A**); 5  $\mu$ m (B–F).

with similarly shaped but smaller conidia than *A. curvatum*. The specimen studied in the present work matches the shape and size of conidia reported by Ellis et al. (1951) for *A. curvatum* var. *minus*, rather than those of *A. curvatum* var. *curvatum*.

**Specimens examined.** Germany: Brandenburg: south of Liberose, on dead leaves of *Carex* sp., 28 Mar. 2018, *R. Jarling* (MA-Fungi 91726).

#### Arthrinium descalsii Pintos & P. Alvarado, sp. nov.

MycoBank: MB 828867 Fig. 6

Etymology. Named to honor the eminent mycologist Enric Descals Callisen.

**Diagnosis.** Sexual morph: *Stromata* forming black fusiform spots that merge with each other with age, forming an erumpent black mass visible at the naked eye,  $2-10 \times 0.2-0.5$  mm in size, with the long axis broken at the top revealing the ostioles of pseudothecia. *Ascomata* pseudothecia, subglobose with a flattened base, arranged in rows, brown to dark brown, 150–220 µm high × 150–250 µm wide (n = 20). *Peridium* with

**Figure 6.** *A. descalsii* **A** stromata on host **B–D** asci with ascospores **E** paraphyses **F**, **G** ascospores **I**, **J** ascospores with sheath **K** colony on MEA 2%; coniogenous cell giving rise to conidia; conidiogenous cells giving rise to conidia and conidia cluster **G** conidia. Scale bars: 200  $\mu$ m (**A**); 10  $\mu$ m (**B–E**); 5  $\mu$ m (**F–J**); 5  $\mu$ m (**L–N**).

several layers of cells arranged in *textura angularis*, with a conspicuous ostiole 50–80 µm in diameter, periphysate. *Hamathecium* paraphyses hyphae-like, septate, hyaline. *Asci* cy-lindrical, clavate, with a short or indistinct pedicel, with rounded apices, measuring (73–)82–95(–111) × (16–)17–20(–23) µm (n = 30). *Ascospores* uniseriate to biseriate, hyaline, smooth-walled, apiosporic, composed of a large curved upper cell and smaller lower cell, fusiform to slightly curved in shape with narrowly rounded ends, guttulated, sometimes with a thick gelatinous sheath, (17–)18–22(–24) × (6–)7–9(–10) µm, and a basal cell 3–5 µm (n = 45). Asexual morph: *Mycelium* hyaline, septate, branched, hyphae 1.5–4.5 µm in diameter *Conidiophores* reduced to the conidiogenous cells. *Conidiogenous cells* solitary on hyphae, ampuliform, hyaline to brown, 5 × 4 µm. *Conidia* brown, smooth, guttulate, globose to ellipsoid (5–)7(–8) µm long (n = 20) in face view, lenticular with a paler equatorial slit and 6-7 µm long in side view (n = 10). *Sterile cells* elongated, sometimes mixed among conidia. *Culture characteristics*: ascospores germinating on MEA 2% within 24–48 h. *Colonies* flat, spreading, with sparse aerial mycelium, pale siena.

**Notes.** Arthrinium descalsii is closely related with A. phragmitis and A. balearicum. It was found in the Mediterranean grass Ampelodesmos mauritanicus, although additional samples are needed before concluding if it could be exclusively associated with this endemic host. Ascospore size is often smaller than that of A. balearicum,  $(23-)26-30(-32) \times (7-)9-10(-12) \mu m$ , but it matches that reported in the protologue of A. phragmitis,  $(20-)22-24(-25) \times (7-)8-9(-10) \mu m$ . However, the conidiophores of A. descalsii are reduced to conidiogenous cells, while those of A. phragmitis measure about  $10-45 \times 1.5-2 \mu m$ , and conidia are slightly smaller in face view, measuring  $(5-)7(-8) \mu m$  long in A. descalsii and up to  $8-10(-11) \mu m$  in A. phragmitis.

Type. Spain: Balearic Islands: Mallorca, es Capdella, on dead stems of *Ampelodes-mos mauritanicus*, 31 Jan. 2018, *A. Pintos* (MA-Fungi 91724 holotype, AP31118A isotype, CBS 145130 ex-type culture).

#### Arthirnium esporlense Pintos & P. Alvarado, sp. nov.

MycoBank MB 828868 Fig. 7

Etymology. In reference to Esporles, the village of Mallorca (Spain) where it was found.

**Diagnosis.** Asexual morph: *Mycelium* consisting of smooth, hyaline, branched septate hyphae about 1.5–4 µm in diameter. *Conidiophores* reduced to conidiogeous cells. *Conidiogenous cells* polyblastic, aggregated in clusters on hyphae, smooth, hyaline to pale brown, ampuliform, cylindrical or lageniform, measuring  $4-22 \times 4-8$  µm. *Conidia* brown, smooth, globose with a pale equatorial slit and (8-)9-12(-13) µm long in frontal view, lenticular and 6-8 µm long in side view (n = 30). *Sterile cells* elongated, sometimes mixed among conidia, paler than them. *Culture characteristics*: colonies flat, spreading, with moderate aerial mycelium, on MEA 2% surface white with yellowish patches, reverse concolour with age.

**Figure 7.** *A. esporlense* **A** colony on MEA **B–F** coniogenous cell giving rise to conidia **G** conidia. Scale bars: 5 µm (**B–G**).

**Type.** Spain: Balearic Islands: Mallorca, Esporles, on dead culms of *Phyllostachys aurea*, 16 July 2017, *A. Pintos* (MA-Fungi 91727 holotype, AP16717 isotype, CBS 145136 ex-type culture).

**Notes.** Arthrinium esporlense is closely related with A. xenocordella and A. kogelbergense. However, A. esporlense does not produce brown setae as A. xenocordella, a species until now known only from soil samples (Crous and Groenewald 2013). Arthrinium esporlense morphologically differs from A. kogelbergense by producing slightly bigger conidiogenous cells ( $4-22 \times 4-8 \mu m vs 5-12 \times 4-5 \mu m$ ). These three species are genetically related (1.00 PP, 96 BP) to the group formed by A. arundinis, A. thailandicum D.Q. Dai & K.D. Hyde, A. malaysianum and the new species A. italicum proposed below.

Apiospora setosa Samuels et al., New Zealand J. Bot. 19: 142 (1981).

Apiospora tintinnabula Samuels et al., New Zealand J. Bot. 19: 142 (1981).

Description. Sexual morph: Stromata black, fusiform, forming rows of densely arranged perithecial ascomata parallel to the main axis of the host, measuring (400-)  $600-2500(-3000) \times (250-)320-450(-550) \ \mu m \ (n = 30). \ Ascomata \ globose \ to \ sub$ globose, with a flattened base, blackish brown, (130-)250-290(-320) µm in diameter (n = 30). Peridium consisting of 3 or 4 layers of cells arranged in textura angularis, dark brown in the external side, hyaline in the inside, ostiole single, central, 10-30 µm in diameter, with a periphysate channel 20-35 µm long. Peryphises broad, colourless. Hamathecium composed of dense hypha-like, broad septate paraphyses, early deliquescing. Asci 8-spored, unitunicate, clavate, broadly cylindrical, pedicel indistinct, apical rounded, thin-walled, without an apical apparatus, measuring (76–)  $85-98(-115) \times (20-)22-26(-28) \ \mu m \ (n = 22).$  As cospores uni- to tri-seriate, hyaline, apiosporic, smooth-walled, fusiform, elliptical, reniform, straight or curved, smoothwalled, sometimes with an internal droplet, bicellular, the widest part located in the central part of the longest cell, some ascospores have a mucose sheath covering them,  $(28-)32-34(-38) \times (8-)9-11(-13)$  (*n* = 35) µm, basal cell 5-7 µm. Asexual morph: Mycelium branched, septate. Conidiomata on host surrounding the stromata of the sexual phase, parallel to the longitudinal axis of the stem, subepidermal, opening by longitudinal splitting of the epidermis and revealing a black conidial mass, (450-)  $630-950(-1000) \times (275-)345-550$  (-600) µm (n = 35). Conidiophore mother cell arising from the stroma, ampuliform, lageniform, cupulate or cylindrical, sometimes with granular pigments at the apex,  $(5)6-10(-16) \times (3-)5-7(-8) \mu m$  (n = 24). Conidiophores basauxic, polyblastic, cylindrical, hyaline to light brown, smooth or with granular pigments in all their length, straight or flexuous, septate or not, sometimes exceeding 90  $\mu$ m in length × 2–4  $\mu$ m wide (n = 43). Conidia globose to obovoid, dark brown, with a central scar at the base, (15-)16-20(-21) in frontal view, (14-)(15-18(-19)) in side view (n = 40). Sterile cells gray, irregularly angled and lobed,  $(15-)17-41(-42) \times (10-)14-23(-25) \mu m$  (*n* = 30). Culture characteristics: colonies in MEA 2% flat, spreading, first white and cottony, later became dark pink, mycelium branched, septate, hyaline, reverse dark.

Notes. After the works of Samuels (1981), Sivanesan (1983), Kirk (1986) and Réblová et al. (2016), *Ap. bambusae*, *Ap. setosa* and *Ap. tintinnabula*, as well as *Scyphos*-

**Figure 8.** *A. hysterinum* lenticular-shaped colonies on host **A** stromata and conidiomata **B**, **C** asci **D**–**G** ascospores **H** colony on MEA **I** black masses of conidia in culture **K**, **L** conidiophore mother cell **M** rugose conidiogenous cell **N**–**P** conidia with lobate sterile cells **O** conidia. Scale bars: 200  $\mu$ m (**A**); 10  $\mu$ m (**B**, **C**); 5  $\mu$ m (**D**–**G**); 200  $\mu$ m (**I**); 5  $\mu$ m (**K**, **M**, **O**); 10  $\mu$ m (**P**).

pora phyllostachydis, are all considered synonyms of *A. hysterinum. Arthrinium hysterinum* is phyllogenetically close to *A. yunnanum* D.Q. Dai & K.D. Hyde, but morphologically differs from the latter because of its thinner asci (76–115 × 20–28 vs 85–100 × 30–35  $\mu$ m). In addition, *A. hysterinum* has longer conidiophores up to 90  $\mu$ m long, and lobed sterile cells while in *A. yunnanum* conidiophores do not exceed 50  $\mu$ m, and sterile cells are lacking.

Specimens examined. New Zealand: Waikato: Paeroa, on dead culm of *Bambusa* sp., 28 Feb. 1980, *E.H.C. McKenzie & P.R. Johnston* (ICMP 6889 ex-type culture).

Spain: Galicia: Santiago de Compostela, on dead culms of *Phyllostachys aurea*, 12 Jan. 2018, *A. Pintos* (MA-Fungi 91731, AP12118). Balearic Islands: Mallorca, Esporlas, on dead culms of *Phyllostachys aurea*, 29 July 2017, *A. Pintos* (MA-Fungi 91729, AP29717). Mallorca, Jardin Botanico de Soller, on dead culms of *Phyllostachys aurea*, 24 Oct. 2017, *A. Pintos* (MA-Fungi 91730, AP2410173). Mallorca, Soller, on dead culms of *Phyllostachys aurea*, 15 Mar. 2018, *A. Pintos* (MA-Fungi 91728, AP15318).

#### Arthrinium ibericum Pintos & P. Alvarado, sp. nov.

MycoBank MB 828869 Fig. 9

Etymology. In reference to the Iberian Peninsula, where the holotype was collected.

Diagnosis. Sexual morph: Stromata solitary to gregarious, immersed or semi-immersed, fusiform to ellipsoid in shape, black, with the long axis broken at the top,  $2-5 \times 0.5-1$  mm. Ascomata perithecial, subglobose with a flattened base, arranged in rows, brown to dark brown, exudating a white cirrhus of ascospores,  $170-300 \mu m$ in diameter and 200-300 µm high. *Peridium* consisting in 3 or 4 layers of cells arranged in textura angularis. Ostiole single, central, 12-30 µm in diameter, with a periphysate channel. Hamathecium composed of dense, septate, branched paraphyses. Asci 8-spored, clavate or cylindrical, lacking an apical apparatus, shortly pedicelate, measuring  $(82-)90-125(-128) \times (14-)15-19(-21) \mu m (n = 30)$ . Ascospores uniseriate to biseriate, hyaline, smooth-walled, apiosporic, composed of a large curved upper cell and small lower cell, fusiform or slightly curved in shape with narrowly rounded ends, uniguttulated, lacking a gelatinose sheath, measuring  $(28-)29-34(-37) \times (5-)6-8(-9)$  $\mu$ m, and a basal cell 5–7  $\mu$ m (*n* = 45). Asexual morph: *Mycelium* hyaline, septate, branched, hyphae 2-4 µm in diameter. Conidiophores reduced to the conidiogenous cells. Conidiogenous cells aggregated in clusters on hypha or solitary, ampuliform or cylindrical,  $6-12 \times 3 \mu m$ . Conidia brown, smooth, globose to ellipsoid (9–)10(–12)  $\mu$ m long (*n* = 30) in face view, lenticular, with a paler equatorial slit, and (6–)7(–8)  $\mu$ m long (n = 40) in side view. Sterile cells elongated, rolled up, sometimes mixed among conidia. Culture characteristics: ascospores germinating on MEA 2% within 24-48 h. Colonies flat, spreading, with sparse aerial mycelium, pale siena with white patches.

Type. Portugal. *Viana do Castelo*: Valença do Minho, on dead culms of *Arundo donax*. 10 Jan. 2018, *A. Pintos* (MA-Fungi 91732 holotype, AP10118 isotype, CBS 145137 ex-type culture).

**Notes.** Arthrinium ibericum belongs to the large clade around A. sacchari, where it shows a relation with the subclade of A. phaeospermum, A. saccharicola, and the modern species A. serenense, A. camelliae-sinensis, A. jiangxiense, A. dichotomanthii, A. obovatum and A. pseudosinense. The size of conidia is more or less similar to that of A. camelliae-sinensis, where these measure about 9.0–13.5 µm in frontal view, but con-

**Figure 9.** *A. ibericum* **A** ascomata with oozing ascospores **B**–**D** asci **E**–**H** ascospores **I** colony on MEA **J**–**M** conidiogenous cells giving rise to conidia **N** sterile cell with conidia **O** conidia. Scale bars: 200 μm (**A**); 10 μm (**B**–**D**); 20 μm (**C**); 5 μm (**E**–**H**); 5 μm (**J**–**O**).

idiogenous cells are a bit smaller in this species, measuring about  $4.0-9.5 \times 3.0-6.0$  µm. *Arthrinium pseudosinense* has slightly smaller asci measuring  $85-100 \times 15-20$  µm, and ellipsoid conidia covered with a mucilaginous sheath. *Arthrinium saccharicola* has hyphae slightly wider, about 3-5 µm. The genetic identity of *A. phaeospermum* is still dubious because of the lack of a proper type, but the lineages of this species in the work of Crous and Groenewald (2013) have slightly smaller conidiogenous cells measuring  $5-10 \times 3-5$  µm, and a different iron-grey colour of colonies in MEA.

#### Arthrinium italicum Pintos & P. Alvarado, sp. nov.

MycoBank MB 828870 Fig. 10

Etymology. In reference to Italy, the country where the holotype was found.

Diagnosis. Sexual morph: Stromata solitary to gregarious, inmersed to erumpent, fusiform, with long axis broken at the top by one or two cracks,  $0.5-4 \times 0.2-0.5$  mm (n = 20). Ascomata uniseriate or irregularly arranged beneath stromata, pseudothecial, black, globose to subglobose with a flattened base, 150–200  $\mu$ m high × 230–300  $\mu$ m wide. Peridium composed of 5 or 6 layers of brown cells arranged in textura angularis, with a conspicuous peryphisate ostiole. *Hamathecium* paraphyses hyphae-like. Asci broadly cylindrical, clavate or subglobose, pedicel indistinct, apically rounded (70- $72-93(-96) \times (14-)15-18(-20) \ \mu m \ (n = 30)$ . Ascospores apiosporic, clavate to fusiform with narrowly rounded ends, composed of a large upper cell and small lower cell, hyaline, smooth-walled, surrounded by a gelatinose sheath, measuring (20-)21-25(-)26 × (5–)6–9(–10) µm, basal cell 3–5 µm (n = 45). Asexual morph: *Mycelium* consisting of smooth, hyaline, branched, septate hyphae 1.5-4 µm in diameter. Conidiophores straight or flexuous, cylindrical, colourless except for the thick brown transversal septa, smooth-walled,  $10-50 \times 1-3 \mu m$ . Conidiogenous cells ampuliform, cylindrical or doliform, hyaline to brown,  $(3-)4-7(-9) \times (1.5-)2-3(-5) \mu m$  (*n* = 30). Conidia brown, smooth, globose in face view, lenticular in side view,  $4-6 \times 3-4 \mu m$  (*n* = 65), with a pale equatorial slit. Culture characteristics: on MEA 2%, sparse aerial mycelia, surface dirty white, reverse pale yellowish.

**Type.** Italy: Sicily: On dead culms of *Arundo donax*, 19 June 2016, *H. Voglmayr* (MA-Fungi 91733 holotype, AP221017 isotype, CBS 145138 ex-type culture).

**Notes.** Arthrinium italicum is phylogenetically close to A. thailandicum, and to a lesser extent to A. malaysianum. Stromata of A. thailandicum are smaller than those of A. italicum, measuring  $0.45-0.99 \times 0.3-0.55$  mm, ascomata are perithecical, its conidiogenous cells are longer (11.5–39 × 2–3.5 µm) and branched, and conidia measure  $5-9 \times 5-8$  µm. The conidia of A. malaysianum are similar in size, but this species does not produce conidiophores.

Other specimens examined. Spain: Balearic Islands: Mallorca, Puerto de Andratx, on dead culms of *Phragmites australis*, 29 Jan. 2018, *A. Pintos* (MA-Fungi 91734, AP29118).

**Figure 10.** *A. italicum* **A**, **B** stromata on host **C** asci **D**, **E**, **G** ascospores **F** ascospores with sheath **H** colony on MEA I–**M** conidiogenous cell giving rise to conidia **N**, **O** conidia. ### Arthrinium marii Larrondo & Calvo, Mycologia 82: 397 (1990) Fig. 11

Description. Sexual morph: Stromata forming black fusiform spots, visible at the naked eye, with a long axis broken at the top revealing the ostioles of pseudothecia, 2-6  $\times$  0.2–0.5 mm in size. Ascomata subglobose, sometimes with a flattened base, brownish to reddish brown, 150-190  $\mu$ m high × 160-250  $\mu$ m wide (n = 20). Peridium with several layers of cells arranged in *textura angularis*, with a conspicuous ostiole 50-7-80 µm diameter, periphysate. Hamathecium paraphyses not prominent, hyphaelike, septate, hyaline. Asci 8-spored, unitunicate, broadly cylindrical to clavate, with rounded apex and a short pedicel,  $(60-)70-100(-115) \times (16-)18-20(-22) \mu m$  (n = 30). Ascospores fusiform to elliptical, with narrowly rounded ends, hyaline, with multiple guttules, surrounded by a mucilaginous sheath,  $(16)19-23(-24) \times (6-)7-8(-10)$  $\mu$ m, basal cell 2–5 (*n* = 30). Asexual morph: *Mycelium* consisting of smooth, hyaline, branched, septate hyphae measuring 1.5-5 µm in diameter. Conidiophores straight or flexuous, cylindrical, colourless except for the thick brown transverse septa, measuring  $10-40 \times 2-3 \mu m$ . Conidiogenous cells ampuliform to cylindrical, hyaline to brown,  $(3-)4-7(-11) \times (1.4-)2-4(-5) \mu m$  (n = 30). Conidia, brown, smooth, granular, globose in face view, lenticular in side view, measuring  $(6-)7-8(-9) \times 4-5(-6) \mu m$ , with a pale equatorial slit. Sterile cells elongated, brown. Culture characteristics: ascospores germinating on MEA 2% within 24-48 h. Colonies flat, spreading, with sparse aerial mycelium, reverse concolour with agA.

**Notes.** Arthrinium marii was proposed by Larrondo and Calvo (1990) who described its asexual morph. This apparently frequent species has been isolated from the atmosphere, pharmaceutical excipients, home dust, and beach sand, as well as from various plant hosts (Crous 2013). In the present work the sexual morph is described for the first time. Genetically, samples identified as *A. marii* seem to represent two distinct clades (Fig. 2), with differences in tub2 and tef1 genes, but it should be further investigated with additional data before concluding if these clades should be interpreted as intraspecific variability, partially isolated lineages, or fully isolated species. Similarly, the incomplete data from the type specimens of *A. hispanicum* and *A. mediterranei* do not allow one to conclude if these apparently related species represent a single taxon or even belong to *A. marii*.

Specimens examined. Austria: Oberösterreich: St. Willibald, on dead culms of *Phragmites australis*, 10 July 2016, *H. Voglmayr*, (MA-Fungi 91738, AP191017).

Italy: Sicily: casa de la Monache, on dead culms of *Phragmites australis*, 16 July 2016, *H. Voglmayr* (MA-Fung 91740, APVog2).

Portugal: Viana do Castelo: Valença do Minho, on dead culms of *Phragmites australis*, 10 Jan. 2018, *A. Pintos* (AP10118A).

Spain: Balearic Islands: Mallorca, Esporlas, on dead culms of *Arundo donax*, 13 July 2017, *A. Pintos* (MA-Fungi 91735, AP13717). Ibidem., 29 July 2017, *A. Pintos* (AP29717). Palma de Mallorca, on *Ampelodesmos mauritanicus*, 11 July 2017, *A. Pintos* (MA-Fungi 91737, AP11717A). Palma de Mallorca, on dead culms of *Phragmites australis*, 26 July 2017, *A. Pintos* (MA-Fungi 91739, AP261017).

#### Arthrinium piptatheri Pintos & P. Alvarado. sp. nov.

MycoBank MB 828871 Fig. 12

Etymology. Named after *Piptatherum*, the host plant from which it was first isolated.

**Diagnosis.** Asexual morph: *Mycelium* consisting of smooth, hyaline, branched, septate hyphae measuring 1–4 µm in diameter. *Conidiophore mother cells* hyaline to brown, aggregated in clusters or solitary on hyphae, ampuliform, cylindrical or doliform,  $4-11 \times 2-5$  µm, growing above one or several hyaline cylindrical cells. *Conidiophore* reduced to a conidiogenous cell. *Conidiogenous cells* basauxic, polyblastic, sympodial, cylindrical, discrete, sometimes branched, smooth-walled, measuring  $6-27 \times 2-5$  µm (n = 25). *Conidia* globose to ellipsoidal, pale brown to brown, with a thin hyaline germ-slit,  $6-8 \times 3-5$  µm (n = 30). *Sterile cells* eloganted, brown, sometimes mixed among conidia,  $13-16 \times 4-5$  µm (n = 30). *Culture characteristics*: on MEA 2%, colonies flat, spreading, with sparse aerial mycelium, reverse concolour with agar.

**Type.** Spain: Balearic Islands: Mallorca: Llucmajor, on dead stems of *Piptatherum miliaceum*, 4 Aug. 2017, *A. Pintos* (MA-Fungi 91745 holotype, AP4817A isotype, CBS 145149 ex-type culture).

**Figure 12.** *A. piptatheri* **A** colony on MEA **B**–**K** conidiogenous cells giving rise to conidia. Scale bars: 5 µm (**B–K**).

**Notes.** Arthrinium piptatheri is genetically close, but genetically distinct from A. marii, A. sacchari, A. guizhouense, A. hispanicum, A. mediterranei, A. longistromum D.Q. Dai & K.D. Hyde, and to a lesser extent A. pseudospegazzinii (Fig. 2) and the clade around A. phaeospermum (Fig. 1). The incomplete genetic data available is probably the cause behind the lack of significant support for some of these taxa. Morphologically, A. piptatheri differs from A. marii because of its sympodial, branched conidiogenous cells. Arthrinium guizhouense has shorter conidiogenous cells (3.5–8.0 µm). Finally, some sequences of Ap. montagnei are related also with this group (Fig. 2), but this species is considered the sexual morph of A. arundinis, with a very different genetic profile in Crous and Groenewald (2013), so its actual identity should be further investigated.

# Arthrinium puccinioides Kunze & J.C. Schmidt, Mykologische (Leizpig) 2: 103 (1823)

Fig. 13

- *Conoplea puccinioides* DE Candolle, 1905, Flore Francaise, Ed. 3, Tome 2, p.73, ex Mérat, Novuvelle Flore des environs de Paris, 1821, p. 16.
- *Goniosporium puccinioides* (Kunze & J. C.Schmidt) Link, in Willdenow, Sp.pl., Edn 4 6(1): 44 (1824).
- *Gonatosporium puccinioides* (Kunze & J. C.Schmidt) Corda, Icon. Fung. (Prague) 3:8 (1839).

**Description.** Asexual morph: *Mycelium* consisting on smooth hyaline, branched, septate hyphae measuring 1.5–5  $\mu$ m in diameter. *Colonies* are small, rounded or ovoid, dark brown, 50–400  $\mu$ m in diameter. *Conidiophore mother cells* subspherical, lageniform or barrel-shaped, 4–5 × 3–5  $\mu$ m (n = 30). *Conidiophores* cylindrical, straight or flexuous, septate, hyaline excepting for the thick brown or dark brown transversal septa, 20–140 × 3–4  $\mu$ m (n = 30). *Conidiogenous cells* cylindrical, occurring between the conidiophore septa, 0.9–1.8  $\mu$ m. *Conidia* dark brown, smooth, polygonal with rounded angles to hemispherical, measuring (8–)9–11(–12) × 8–9  $\mu$ m, with one or two concentric pale rings. *Sterile cells* spherical, triangular or polygonal, with refractive bodies inside, paler than conidia, 6–9  $\mu$ m in diameter. *Culture characteristics* colonies flat spreading on MEA 2%, with moderate aerial mycelium, reverse whitish, no esporulate on culture.

**Notes.** Arthrinium puccinioides is the only species of Arthrinium with polygonal conida. It shows a genetic relationship with other species found in *Carex* sp. hosts, such as *A. caricicola*, *A. curvatum* var. *minus*, *A. japonicum* or *A. sporophleum*. The present sample fits the original description of *A. puccinioides* by Kunze and Schmidt (1823) as well as those by Ellis et al. (1951), Ellis (1965), and Scheuer (1996).

Specimens examined. Germany: *Berlin*: Köpenick, Stellingdamm, on dead leaves of *Carex arenaria*, 26 April 2017, *R. Jarling* (MA-Fungi 91746, AP26418).

**Figure 13.** *A. puccinioides* **A** colony on host **B** colony on MEA **C** conidiophore mother cell **D**–**F** conidiophore bearing conidia **G**–**H** conidia in side view. Scale bars: 100 μm (**A**); 5 μm (**C**–**H**).

## Arthrinium sporophleum Kunze, 1823, in Kunze & Schmidt's Mykologische Hefte, 2, p. 104; Fries, 1832, Systema Mycol., 3, p. 377 Fig. 14

Sporophleum gramineum Nees, 1824, apud Link in Linne, Species Plantarum, ed. 4 (Willdenow's), 6, 1, p. 45.

*Torula eriophori* Berkeley, 1836, Fungi in J. E. Smith's English Flora, 5 (2), p. 359. *Arthrinium sporophleoides* Fuckel, Jb. nassau. Ver. Naturk. 27–28: 78 (1874) [1873–74]

**Description.** Asexual morph: *Mycelium* consisting on smooth hyaline branched hyphae, 2–5 µm in diameter. *Colonies* oval to irregular, dark blakish brown, 300–1200 × 150–650 µm. *Conidiophore mother cells* sub-cylindrical, hyaline to pale brown, measuring 5–7 × 5–7 µm (n = 20). *Conidiophores* straight to flexuous, cylindrical, hyaline except for the thick brown to dark brown transversal septa, 30–130 × 2–4 µm (n = 20). *Conidia* brown, smooth, lemon-shaped in face view, measuring (10–)11–14(–15) × (5–)6–8(–9) µm (n = 45), triangular with the outer edge curved and rounded angles in side view, measuring 5–8 µm thick. *Sterile cells* paler than conidia, subspherical or triangular, 5–8 µm wide. *Culture characteristics*: on MEA 2% colonies cottony, white with grey patches, reverse pale grey.

**Figure 14.** *A. sporophleum* **A** colony on host **B** conidiophore mother cells **C–E** conidiophore mother cells with conidiophore bearing conidia, **F** with sterile cell **F–H** conidia **I** colony on MEA. Scale bars: 100  $\mu$ m (**A**); 5  $\mu$ m (**B–H**).

**Notes.** Arthrinium sporophleum is the only species of Arthrinium with lemonshaped conidia. Kunze (1823) considered that Sporophleum gramineum represents a synonym of this species, and Cooke (1954) considered A. sporophleoides Fuckel a synonym of this species too. The only sample analyzed in the present work fits the descriptions of this species by Kunze (1823), Ellis et al. (1951), Ellis (1965) and Scheuer (1996). This sample was found in *Juncus* sp., but this remarkable species has been often reported from *Carex* sp. hosts (Ellis 1965). Interestingly, other species occurring in *Carex* sp. present also conidia with unusual shapes, e.g. A. puccinioides (polygonal), A. curvatum var. minus (curved), and A. caricicola or A. japonicum (fusiform).

**Specimens examined.** Spain: Balearic Islands: Mallorca, Escorca, on dead leaves of *Juncus* sp., 21 Feb. 2018, *A. Pintos 21218* (MA-Fungi 91749).

**Other specimens studied.** *Arthrinium arundinis*: Spain: Galicia: Santiago de Compostela, city garden, culms of *Bambusa* sp., 11 Jan. 2018, *A. Pintos 11118A* (MA-Fungi 91722). *Arthrinium phragmitis*: Spain: Balearic Islands: Mallorca, Esporles, on dead culms of *Arundo donax*, 29 July 2017, *A. Pintos* (MA-Fungi 91744, AP29717A). Ibidem., on dead stem of *Phragmites australis*, 3 Feb. 2018, *A. Pintos* (MA-Fungi 91743,

AP3218). Jardin Botanico de Soller, on dead culms of *Arundo donax*, 24 Oct. 2017, *A. Pintos* (MA-Fungi 91742, AP2410172A). Puigpunyent, on dead culms of *Phragmites australis*, 28 Dec. 2017, *A. Pintos* (MA-Fungi 91741, AP281217A1). *Arthrinium rasikravindrii*: Spain: *Balearic Islands*: Mallorca, Esporlas, on dead culms of *Phyllostachys aurea*, 8 Aug. 2017, *A. Pintos* (MA-Fungi 91747, AP8817). Jardin Botanico de Soller, on dead culms of *Bambusa* sp., 24 Oct. 2017, *A. Pintos* (AP2420171). Soller, on dead culms of *Phyllostachys aurea*, 10 Apr. 2018, *A. Pintos* (MA-Fungi 91748, AP10418).

#### Discussion

Arthrinium is thought to represent the asexual morph of Apiospora because genetic data of Ap. montagnei (type species of Apiospora, Müller and Arx 1962) grouped together with other species of Arthrinium (Crous and Groenewald 2013; Senanayake et al. 2015; Réblová et al. 2016). Unfortunately, no data from the type species of Arthrinium, A. caricicola, was available to confirm this synonymy. In the present work, a phylogenetic relationship was found between a specimen identified as A. caricicola and other species of Arthrinium mainly occurring in Carex sp., such as A. curvatum var. minus, A. japonicum, A. puccinioides and A. sporohleum. Moreover, this clade was not significantly related with all other species of Arthrinium and Apiospora found in other hosts or substrates, suggesting that both clades could be interpreted as independent genera sister to Nigrospora. In this case, the synonymy between Arthrinium and Apiospora could be rejected, requiring new combinations. However, this hypothesis should be further confirmed after the analysis of the remaining known species occurring in Cyperaceae hosts, such as A. austriacum, A. fuckelii, A. globosum, A. kamtschaticum, A. morthieri, A. muelleri, or A. naviculare.

Arthrinium species have been found in several different plant hosts (Ramos et al. 2010; Sharma 2014), where they sometimes cause plant diseases (Martínez-Cano et al. 1992; Mavragani et al. 2007; Chen et al. 2014; Li et al. 2016). They are also isolated from lichens (He and Zhang 2012), marine algae (Suryanarayanan 2012), soil (Singh et al. 2013) and can even cause infections in humans (Rai 1989; Zhao et al. 1990; Hoog et al. 2000). In the present study six new species of *Arthrinium* are proposed: A. balearicum, A. descalsii, A. esporlense, A. ibericum, A. italicum, and A. piptatheri, all of them found in the Mediterranean biogeographical region, excepting for A. ibericum, which was found in the Atlantic areas of Spain. All these new taxa were found growing on plant hosts of the Poaceae family, such as Arundo donax or Piptatherum miliaceum. However, A. marii was the species most frequently found in the surveys, occurring on the Poaceae grasses Ampelodesmos mauritanicus and Phragmites australis, in agreement with the data reported by Crous and Groenewald (2013). Arthrinium phragmitis was found also on *Phragmites australis* and less commonly in *Arundo donax*, while A. hysterinum and A. rasikravindrae were associated with the Poaceae bamboos Phyllostachys aurea and Bambusa sp. Several colonies of A. rasikravindrae were found growing on *Phyllostachys aurea* as well, where they developed acervular conidiomata, a feature not observed in the protologue of this species, and therefore not considered diagnostic, in the same way as conidial shape, presence of setae, or lobate sterile cells.

Apiospora tintinnabula (Samuels et al. 1981) is considered a synonym of A. hysterinum (Sivanesan 1983; Kirk 1986). Multigenic data from the ex-type culture ICMP 6889 of Ap. tintinnabula was obtained so as to compare it with the newly found specimens of A. hysterinum, and no significant difference could be found. Interestingly, the collections of A. hysterinum studied in the present work presented sterile lobed cells, a feature not mentioned in the protologue of Ap. tintinnabula. The genetic data available from Ap. setosa and Ap. bambusae (28S and tub2) are not significantly different from those of A. hysterinum and Ap. tintinnabula, although additional markers would be needed to confirm a putative synonymy.

#### Acknowledgements

We thank Dr Hermann Voglmayr for his valuable advice, Chris Yeates and Martin Bemmann for providing literature, and Äsa Kruys for providing details about type collection of *Arthrinium caricicola*.
