Abstract

During a survey of saprobic fungal niches in Southwestern China, eighteen ascomycetous collections of *Nigrograna* (Nigrograna ceae, Pleosporales, Dothideomycetes) were found on dead branches of medicinal plants. These taxa were characterized and identified based on morphological and culture characteristics, and phylogenetic analyses of a combined the internal transcribed spacer region of rDNA (ITS), nuclear large subunit rDNA (28S, LSU), RNA polymerase second-largest subunit (*rpb2*), nuclear small subunit rDNA (18S, SSU), and translation elongation factor 1-alpha (*tef1-α*) sequence dataset also confirmed their placement. As a result, four novel species, namely *Nigrograna camelliae*, *N. guttulata*, *N. longiorostiolata* and *N. neriicola* were described. Additionally, four new host records of *N. acericola*, *N. magnoliae*, *N. oleae* and *N. thymi* were introduced. Furthermore, this study addresses the taxonomic status of *N. trachycarpi*, proposing its synonymy under *N. oleae*. Detailed illustrations, descriptions and informative notes for each newly identified taxon and novel host record are provided in this study.

Key words: 4 new taxa, Dothideomycetes, multi-locus, phylogeny, sexual morph, taxonomy

Introduction

The utilization of medicinal plants is integral to disease prevention and treatment in human life (Nalawade et al. 2003; Cole et al. 2007; Schmidt 2017; Rahman et al. 2019). These plants harbor diverse biological compounds that hold potential for drug development due to their rich reservoir of bioactive ingredients (Samy and Gopalakrishnakone 2007; Ali et al. 2021; Atanasov et al. 2021). Southwestern China, recognized as one of the primary regions for traditional Chinese herbal medicine, boasts remarkable diversity in medicinal plant species. This diversity is largely driven by the region's unique karst landforms, which

* These authors contributed equally to this work.

promote species differentiation and abundance (Huang et al. 2012; Taylor et al. 2014; Lu et al. 2018; Guo et al. 2020; Shan et al. 2022). Recent studies in Southwest China have revealed novel micro-fungi species associated with medicinal plants, including pathogens (Abtahi and Nourani 2017), saprobes (Du et al. 2022a; Sun et al. 2023; Wu et al. 2024) and endophytes (Helaly et al. 2018; Keshri et al. 2021; Du et al. 2022b), highlighting the potential of these plants as reservoirs for discovering fungal diversity.

Nigrograna ceae (Pleosporales, Dothideomycetes) was established by Jaklitsch and Voglmayr (2016) based on morpho-molecular evidence, with *Nigrograna* as the type genus. The divergence of Nigrograna ceae is established at approximately 79 (44–124) Mya in crown age and 131 (86–180) Mya in stem age (Liu et al. 2017). Initially, the genus *Nigrograna* was proposed by de Gruyter et al. (2012) to accommodate *Pyrenochaeta mackinnonii* (a pathogenic species in humans isolated from a mycetoma patient), which was later synonymized as *Nigrograna mackinnonii*. However, phylogenetic studies revealed that *N. mackinnon*ii was closely related to *Biatriospora marina*, the type species of the monotypic genus *Biatriospora* (Ahmed et al. 2014), leading to the reclassification of *N. mackinnonii* as *Biatriospora mackinnonii* (Ahmed et al. 2014). Jaklitsch and Voglmayr (2016) subsequently proposed the family Nigrograna ceae, describing three new taxa that differed significantly from *Biatriospora* in morphology and ecology. Hongsanan et al. (2020) further revised the taxonomic status of *Biatriospora* and *Nigrograna*, suggesting that both genera should be retained. To date, there are 37 species epithets of *Nigrograna* listed in Index Fungorum (http://www.indexfungorum.org/Names/Names.asp; accessed 7 September 2024).

Most members of *Nigrograna* have cryptic morphological characters, leading Jaklitsch and Voglmayr (2016) to classify them as cryptic species. The sexual morphs of *Nigrograna* are characterized by having globose to subglobose ascomata with ostiole, multi-layered peridium, clavate and fissitunicate asci, fusoid to narrowly ellipsoid, straight or curved, septate, and smooth or verruculose ascospores (Jaklitsch and Voglmayr 2016; Zhang et al. 2020; Lu et al. 2022). In contrast, the asexual morphs are defined by globose to subglobose or pyriform pycnidia, filiform and branched conidiophores, hyaline, phialidic and discrete conidiogenous cells, sub-hyaline, aseptate and ellipsoidal conidia (de Gruyter et al. 2012; Jaklitsch and Voglmayr 2016; Lu et al. 2022). The life modes of *Nigrograna* species are diverse, ranging from endophytic and saprobic to pathogenic (in human) (Kolařík 2018; Zhao et al. 2018; Lu et al. 2022; Li et al. 2023). These species have been reported from various hosts in terrestrial, marine, and freshwater habitats (Hyde et al. 2017; Tibpromma et al. 2017; Dayarathne et al. 2020; Lu et al. 2022; Bundhun et al. 2023; Hu et al. 2023; Li et al. 2023; Senanayake et al. 2023; Shu et al. 2023), underscoring the broad ecological diversity of this genus. In recent years, an increasing number of new species and records of *Nigrograna* have been reported from various hosts in China. Most of these species have been identified as saprotrophic fungi from terrestrial habitats (Tibpromma et al. 2017; Boonmee et al. 2021; de Silva et al. 2022; Lu et al. 2022; Hu et al. 2023; Li et al. 2023; Liu et al. 2024; Ren et al. 2024; Xu et al. 2024). However, reports of *Nigrograna* occurring on medicinal plants are

limited. Given the ecological and economic importance of these plants, it is essential to explore the taxonomy and phylogeny of *Nigrograna* species associated with medicinal flora. Such investigations will deepen our understanding of fungal diversity in these specialized niches and may reveal new insights into the potential applications of these fungi.

This study focuses on elucidating the diversity of Nigrogranaceae in Southwestern China, identifying eight species associated with medicinal plants. We aim to describe these novel findings and contribute to the understanding of fungal diversity in this region. Through a combination of morphological comparisons and multi-locus phylogenetic analyses, we introduce four new species and four new host records, supported by both morphological and phylogenetic evidence.

Materials and methods

Collection and examination of specimens

Specimens in this study were collected from medicinal plants of nine families (Apocynaceae, Berberidaceae, Buxaceae, Celastraceae, Eucommiaceae, Fabaceae, Primulaceae, Rutaceae and Theaceae) in Southwest China during 2021 and 2023, viz., (1) Guizhou Province (26°30'43"N–26°32'18"N, 106°39'32"E–106°41'48"E, elevation 1,127–1,155 m); (2) Sichuan Province (29°29'1"N–31°8'4"N, 103°2'23"E–104°14'19"E, elevation 504–1,200 m); (3) Yunnan Province (21°55'53"N–25°14'27"N, 101°23'19"E–102°44'28"E, elevation 505–1,922 m). The sampling information (date, host, place, GPS, etc.) was recorded. Samples were packaged in envelopes and brought to the laboratory following the method described by Senanayake et al. (2020). Morphological observations were made using a Motic SMZ (Stereoscopic Zoom Microscope) 168 Series dissecting microscope (Motic, Xiamen, China) for fungal structures on a natural substrate. Fruiting bodies were collected using a syringe needle and transferred to a drop of tap water on a clean slide. The features were examined and photographed using a Nikon ECLIPSE Ni-U compound microscope fitted with a Nikon DS-Ri2 digital camera. Measurements were made with the Tarosoft Image Frame Work v. 0.9.7 software following the procedures outlined by Liu et al. (2010), and images used for photo plates were processed with Adobe Photoshop CC 2018 software (Adobe Systems, San Jose, CA, USA). Single spore isolations were made on potato dextrose agar (PDA, Oxoid) or water agar (WA, Oxoid) and later transferred onto new PDA plates following the methods described in Senanayake et al. (2020). Incubation and cultural growth were observed at 25 °C in dark and pure cultures were obtained.

Herbarium specimens were deposited in the Herbarium of Cryptogams, Kunming Institute of Botany Academia Sinica (HKAS), Kunming, China, and the herbarium of University of Electronic Science and Technology (HUEST), Chengdu, China. The pure cultures obtained in this study were deposited in the China General Microbiological Culture Collection Center (CGMCC) in Beijing, China and the University of Electronic Science and Technology Culture Collection (UESTCC), Chengdu, China. Names of the new taxa were registered in MycoBank (http://www.mycobank.org/).

DNA extraction, PCR amplification and sequencing

Isolates were grown in PDA medium at 25 °C in dark for three weeks to one month. Fungal mycelia were scraped off and transferred to 1.5 mL microcentrifuge tubes using a sterilized lancet for genomic DNA extraction. Fungal DNA was extracted from mycelia (about 50–100 mg) using the Trelief TM Plant Genomic DNA Kit (TsingKe Co., Beijing, China). Five different gene regions were amplified by Polymerase Chain Reaction (PCR). The internal transcribed spacer region of rDNA (ITS), nuclear large subunit rDNA (28S, LSU), nuclear small subunit rDNA (18S, SSU), RNA polymerase second-largest subunit (*rpb2*) and translation elongation factor 1-alpha (*tef1-α*) were selected for the study. The primers used were LR0R/LR5 for LSU (Vilgalys and Hester 1990), NS1/NS4 for SSU (White et al. 1990), ITS5/ITS4 for ITS (White et al. 1990), fRPB2-5F and fRPB2-7cR for *rpb2* (Liu et al. 1999) and TEF1-983F/TEF1-2218R for *tef1-α* (Rehner and Buckley 2005). Amplifications were performed in a 25 µL reaction volume containing 9.5 µL of ddH_2O, 12.5 µL of 2× Taq PCR Master Mix with blue dye (Sangon Biotech, Shanghai, China), 1 µL of DNA template and 1 µL of each primer. The amplification condition for ITS, LSU, SSU, and *tef1-α* consisted of initial denaturation at 94 °C for 3 min, followed by 40 cycles of 45 s at 94 °C, 50 s at 55 °C and 1 min at 72 °C, and a final extension period of 10 min at 72 °C. The amplification condition for the *rpb2* gene consisted of initial denaturation at 95 °C for 5 min; followed by 37 cycles of 15 s at 95 °C, 50 s at 56 °C and 2 min at 72 °C, and a final extension period of 10 min at 72 °C. The PCR product purification and sequencing were performed at Beijing Tsingke Biotechnology (Chengdu) Co., Ltd., Chengdu, China.

Phylogenetic analyses

In this study, the taxa included in the phylogenetic analyses were selected and obtained from previous studies and GenBank (Table 1), with a total of 67 taxa. *Occultibambusa pustula* (MFLUCC 11-0502) and *O. bambusae* (MFLUCC 13-0855) (Occultibambusaceae, Pleosporales) were selected as outgroup taxa. Single-locus alignments were made in MAFFT v. 7 (http://mafft.cbrc.jp/alignment/server/) (Katoh and Standley 2013) and checked visually using AliView (Larsson 2014). The alignments were trimmed using trimAl v 1.2 (Capella-Gutierrez et al. 2009). Five single-locus alignments were combined using SequenceMatrix 1.7.8 (Vaidya et al. 2011). Maximum likelihood (ML) and Bayesian inference (BI) analyses were employed to assess phylogenetic relationships as detailed in Dissanayake et al. (2020).

ML analyses were performed with RAxML-HPC v.8 on XSEDE (8.2.12) (Stamatakis 2006; Stamatakis et al. 2008) through the CIPRES Science Gateway V. 3.3 (https://www.phylo.org/portal2/login!input.action) (Miller et al. 2010). The tree search included 1,000 non-parametric bootstrap replicates; the best scoring tree was selected among suboptimal trees from each run by comparing likelihood scores under the GTRGAMMA substitution model. The resulting replicates were plotted onto the best scoring tree obtained previously. ML bootstrap values equal to or greater than 75% were marked near each node.

BI was performed in MrBayes 3.2.6 (Ronquist et al. 2012). The program MrModeltest 2 v. 2.3 (Nylander 2008) was used to determine the best nucleotide

substitution model for each data partition. The evolutionary model of SYM+I+G substitution model was selected for ITS, HKY+G substitution model was selected for SSU, and GTR+I+G substitution model was selected for LSU, *rpb2* and *tef1-α*. Posterior probabilities (PP) (Rannala and Yang 1996) were determined by Markov chain Monte Carlo sampling (MCMC). Six simultaneous Markov chains were run for 10 million generations, and trees were sampled every 1,000 th generation. The first 25% of saved trees, representing the burn-in phase of the analysis, were discarded. The remaining trees were used for calculating posterior probabilities in the majority rule consensus tree (Larget and Simon 1999). PP values equal to or greater than 0.95 were marked near each node.

Phylogenetic trees were printed with Fig Tree v. 1.4.4 (http://tree.bio.ed.ac.uk/software/figtree/) and the layout was created in Adobe Illustrator CS6 software (Adobe Systems, USA). The new sequences generated in this study were deposited in GenBank (Table 1).

Phylogenetic results

In this study, five loci, ITS, LSU, *rpb2*, SSU, and *tef1-α*, were used to determine the phylogenetic placement of the new collections. The concatenated matrix was comprised of 69 taxa with a total of 4,236 bp characters (ITS: 1–473 bp; LSU: 474–1,306 bp; *rpb2*: 1,307–2,331 bp; SSU: 2,332–3,335 bp; *tef1-α*: 3,336–4,236 bp) including gaps. Single-locus analyses were carried out to compare the topologies and clade stabilities, respectively. The results showed that ML and BI were similar in topology without significant conflicts. The best RAxML tree with a final likelihood value of -20,464.246121 is presented in Fig. 1. RAxML analysis yielded 1,200 distinct alignment patterns and 26.42% of undetermined characters or gaps. Estimated base frequencies were as follows: A = 0.247595, C = 0.247214, G = 0.264771, T = 0.240420, with substitution rates AC = 1.651782, AG = 5.572876, AT = 1.491922, CG = 1.179397, CT = 11.546850, GT = 1.000000; gamma distribution shape parameter alpha = 0.139617. Tree-Length = 1.453662. The final average standard deviation of split frequencies at the end of total MCMC generations for BI analysis was 0.009978 (the critical value for the topological convergence diagnostic is below 0.01).

Representatives of all the species of *Nigrograna* were including in our phylogenetic analysis (Fig. 1). Four strains (CGMCC 3.25627, UESTCC 23.0203, UESTCC 23.0190 and UESTCC 23.0206) were nested with *N. magnoliae* (ex-type strain MFLUCC 20-0020 and MFLUCC 20-0021), and strains, UESTCC 23.0208 and UESTCC 23.0191, UESTCC 23.0210 and UESTCC 23.0194, clustered with *N. acericola* (ex-type strain, CGMCC 3.24957) and *N. thymi* (ex-type strain, MFLUCC 14-1096), respectively. *Nigrograna trachycarpi* (GMB0499 and GMB0505) was synonymized under *N. oleae*, these two strains of *N. trachycarpi* and our two isolates (UESTCC 23.0209 and UESTCC 23.0193) grouped with ex-type strain of *N. oleae* (CGMCC 3.24423) with maximum support (100% MLBS/1.00 BIPP).

Nigrograna camelliae (CGMCC 3.25625 and UESTCC 23.0197) and *N. guttulata* (CGMCC 3.25689 and UESTCC 23.0295) were sister to *N. coffeae* (ex-type strain ZHKUCC 22-0210 and ZHKUCC 22-0211) and *N. peruviensis* (ex-type strain CCF 4485), respectively. They formed two distinct clades with 100% MLBS/1.00 BIPP and 63% MLBS/0.98 BIPP, respectively. *Nigrograna neriicola* (CGMCC 3.25624 and UESTCC 23.0195) was sister to *N. schinifolii* (ex-type strain GMB0498 and GMB0504) and formed a strongly supported monophyletic lineage (96% MLBS/1.00 BIPP). *Nigrograna longiorostiolata* (CGMCC 3.25626 and UESTCC 23.0200) formed a distinct lineage with high bootstrap support (100% MLBS/1.00 BIPP).

Taxonomy

***Nigrograna magnoliae* Wanas, PLoS One, 15(7): 10 (2020)**
MycoBank No: 557331
Fig. 2

Description. ***Saprobic*** on dead branches of *Buxus sinica* (Buxaceae). **Sexual morph:** ***Ascomata*** 204–326 µm wide, 140–220 µm high ($\bar{x}$ = 248 × 187 µm, n = 20), solitary or gregarious, scattered, immersed to semi-immersed, with only ostiolar necks visible on the host surface, trigonoid, uniloculate, perithecioid, globose to subglobose, brown to dark brown, with an ostiole. ***Ostiole*** central or eccentric,

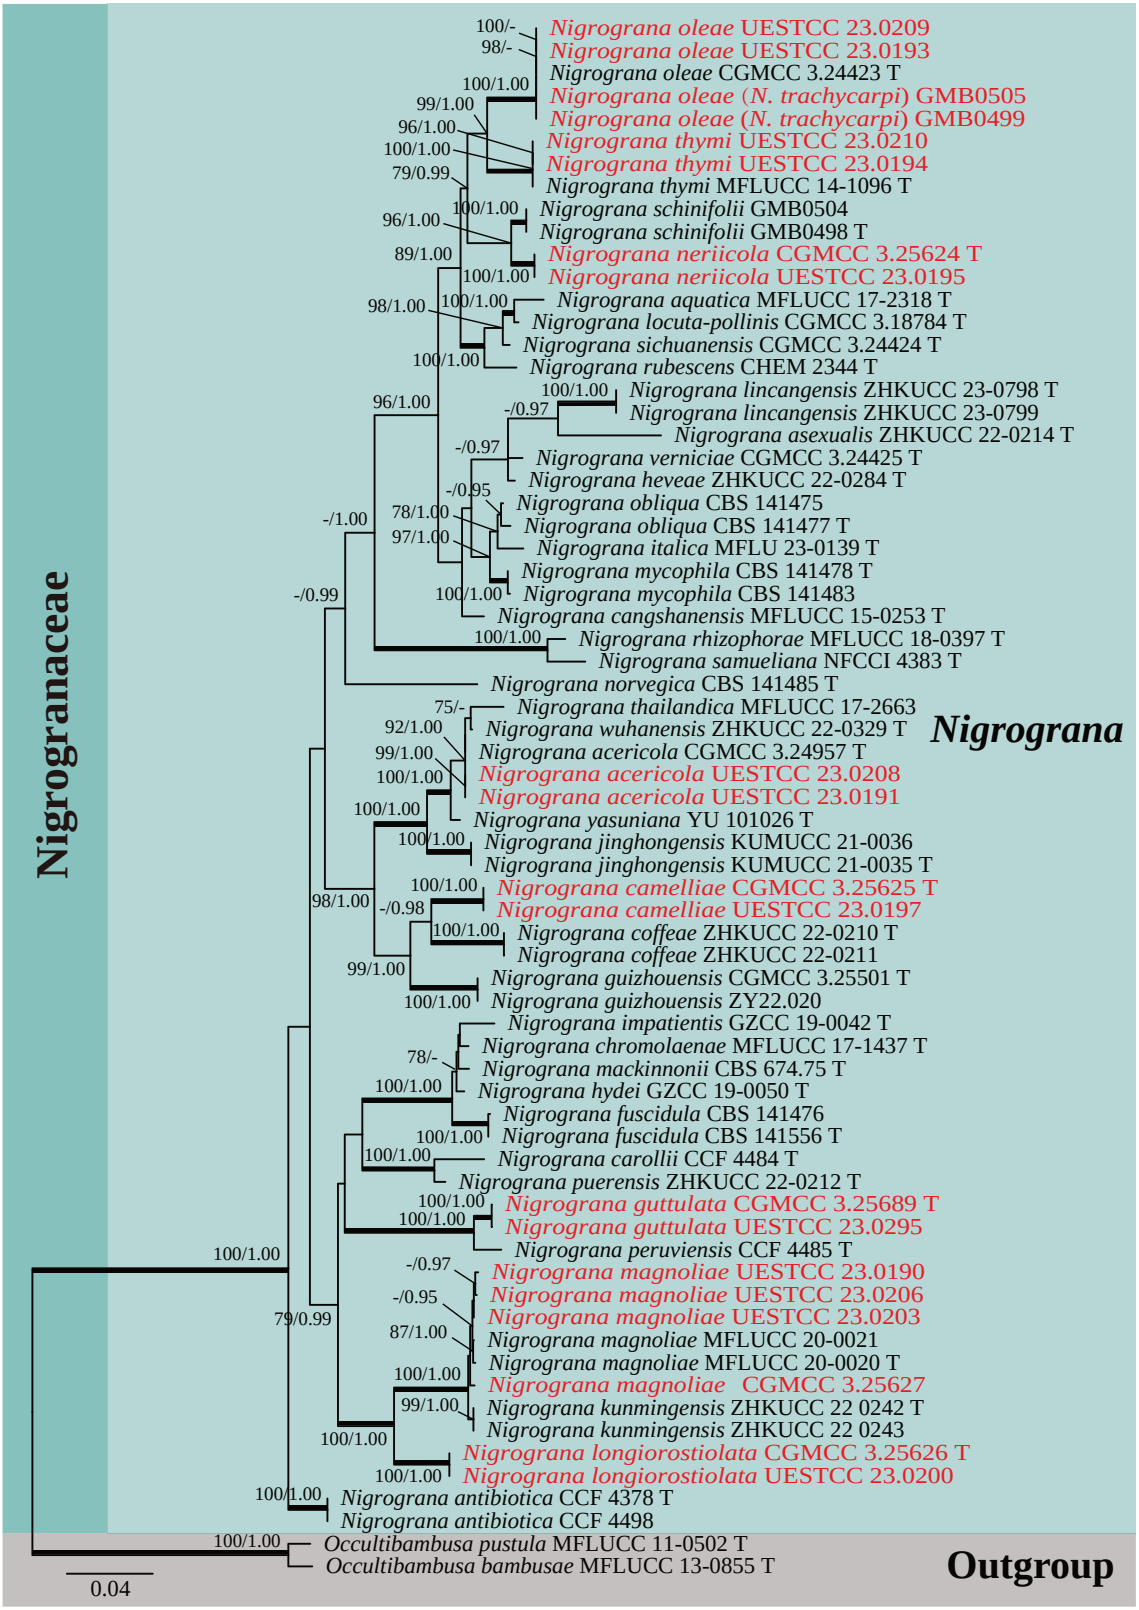

Figure 1. Phylogenetic tree constructed from maximum likelihood (RAxML) analyses of a combined ITS, LSU, *rpb2*, SSU, and *tef1-a* sequence data for selected genera within the family Nigrograniaceae (Pleosporales, Dothideomycetes). Branches support for Maximum likelihood (MLBS) equal to or greater than 75% and Bayesian inference posterior probabilities (BIPP) equal to or greater than 0.95 are marked above or below nodes as MLBS/BIPP. The abbreviation T indicates the ex-type strain. Species names and culture collections in red are newly collected taxa and synonymized isolates. The tree was rooted with *Occultibambusa pustula* (MFLUCC 11-0502) and *O. bambusae* (MFLUCC 13-0855).

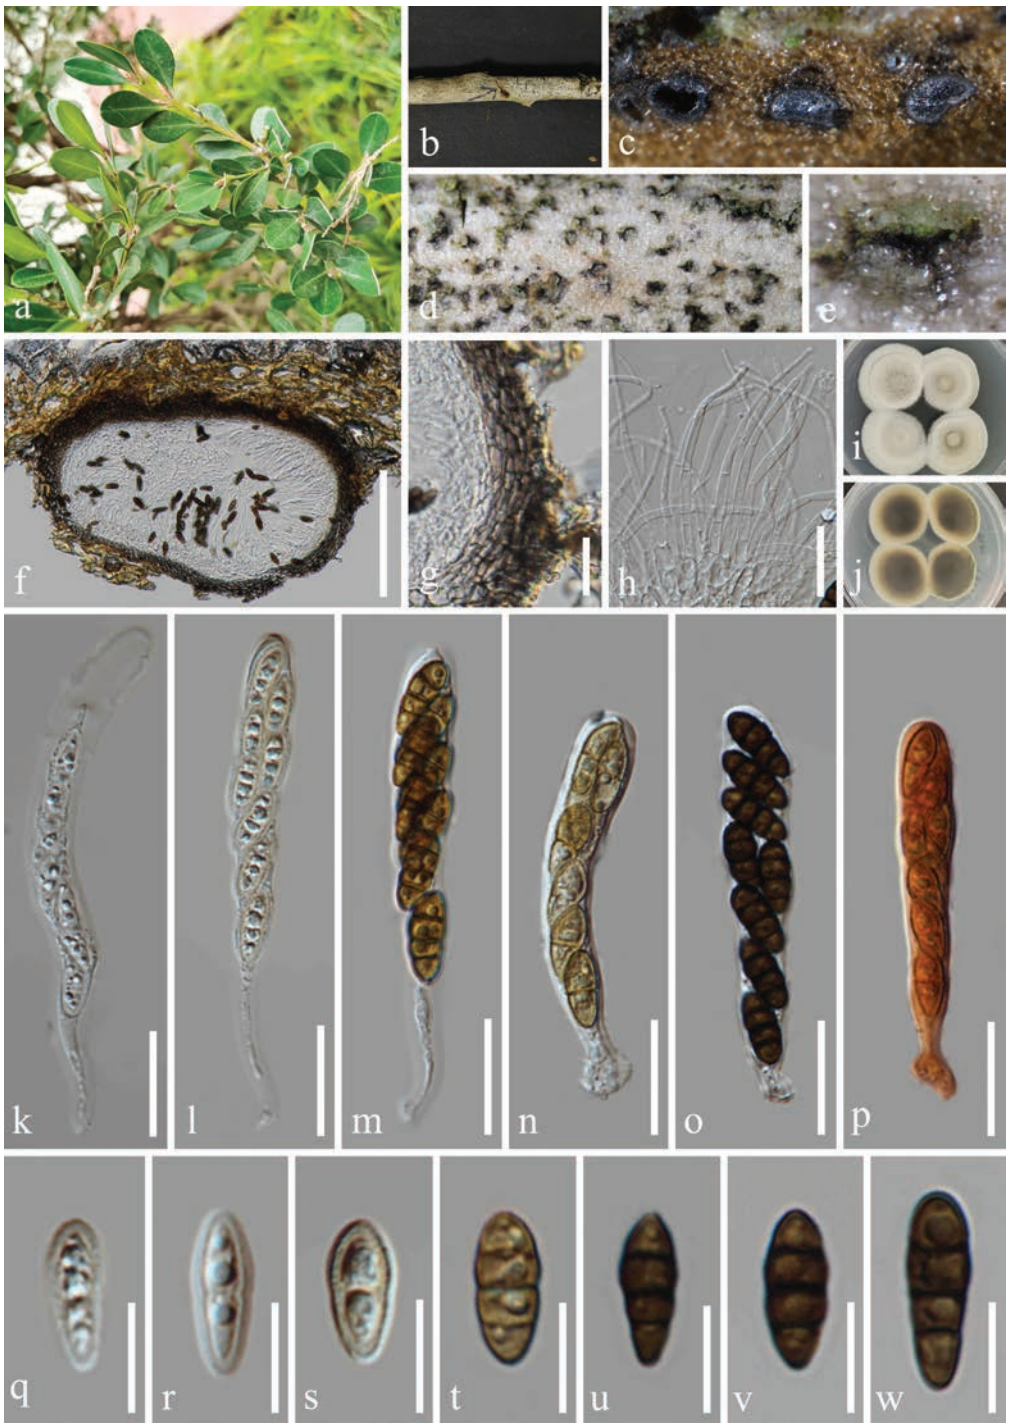

Figure 2. *Nigrograna magnoliae* (HUEST 23.0203, new host record) **a** host *Buxus sinica* **b** branch of *Buxus sinica* **c–e** appearance of ascomata on host surface **f** vertical section through ascoma **g** peridium **h** hamathecium **i, j** colonies on PDA, above (**i**) and below (**j**) **k–o** asci **p** asci in Congo red **q–w** ascospores. Scale bars: 100 µm (**f**); 20 µm (**g, h**, **k–p**); 10 µm (**q–w**).

brittle. ***Peridium*** 15–23 µm ($\bar{x}$ = 18 µm, n = 20) composed of angular cells, consisting 4–5 layers, brown to dark brown thick-walled cells of outer layer, hyaline to subhyaline thin-walled cells of inner layer. ***Hamathecium*** 1–3 µm ($\bar{x}$ = 2 µm, n = 20) wide, composed of numerous, filamentous, hyaline, aseptate or separate, rarely branched, smooth-walled pseudoparaphyses. ***Asci*** 57–103 × 8–11 µm ($\bar{x}$ = 72.5 × 10 µm, n = 30), 8-spored, bitunicate, fissitunicate, clavate to long cylindric-clavate, short cylindrical pedicellate with a swollen base, apically rounded, with a minute

ocular chamber. ***Ascospores*** 13–19 × 4.5–6 µm ($\bar{x}$ = 14.5 × 5 µm, n = 50), 1–2-seriate, partially overlapping, fusoid to ellipsoid, tapering towards the blunt ends, or blunt at both ends, guttulate, smooth-walled, olivaceous to yellowish-brown when young, 1-septate; deeply constricted at septa, becoming 3-septate, brown to dark brown when mature, without appendages. **Asexual morph:** Undetermined.

Culture characteristics. Ascospores germinated on PDA within 24 h, and germ tubes produced from basal cell. Colonies growing on PDA reached 32–33 mm in diameter after three weeks at 25 °C in dark, white in the whole colony from above, and slightly raised in the center, circular, flat, edge entire, margin well-defined; in reverse, grayish black in the center, off-white at the margin, the color gradually lightens from center to edge, no pigmentation on PDA.

Material examined. China • Yunnan Province, Kunming City, Panlong District, Kunming Botanical Garden. 25°8'27"N, 102°44'24"E, elevation 1,922 m, on dead branches of medicinal plant *Buxus sinica* (Rehder & E. H. Wilson) M. Cheng (Buxaceae), 11 November 2022, H.Z. Du, S735 (HUEST 23.0203), living culture UESTCC 23.0203; • ibid., Sichuan Province, Chengdu City, High-tech West District, Yaobo Park, 30°43'57"N, 103°56'21"E, elevation 504 m, on dead branches of medicinal plant *Eucommia ulmoides* Oliv. Notes. *Nigrograna magnoliae* was introduced by Wanasinghe et al. (2020) with both asexual and sexual morphs reported in China. The host distribution of this species is presented in Table 2. Our collections are identical to *N. magnoliae* based on morphology and phylogeny. Therefore, we reported it as new host records from medicinal plants of *Buxus sinica*, *Camellia sinensis*, *Eucommia ulmoides* and *Mahonia bealei* in China.

***Nigrograna longiorostiolata* H.Z. Du & Jian K. Liu, sp. nov.**
MycoBank No: 854177
Fig. 3

Etymology. The epithet '*longiorostiolata*' refers to the longer-ostiolate of ascomata.

Holotype. HKAS 131311

Description. ***Saprobic*** on dead branches of *Citrus medica* (Rutaceae). **Sexual morph:** ***Ascomata*** 222–293 µm wide, 144–486 µm high ($\bar{x}$ = 264 × 303 µm, n = 20), solitary, scattered, immersed, visible as black dots on the host surface, uniloculate, globose to subglobose, sometimes obpyriform with a long ostiole. ***Ostioles*** 175–302 µm long, 83–128 µm wide ($\bar{x}$ = 263 × 102 µm, n = 20) central or eccentric, longer, with a crest-like apex, filled with hyaline or slightly brown periphyses. ***Peridium*** 17–32 µm ($\bar{x}$ = 23.5 µm, n = 20) composed of *textura prismatica* cells, consisting 3–4 layers, brown to dark brown of outer layer, hyaline to subhyaline of inner layer. ***Hamathecium*** 1–2 µm ($\bar{x}$ = 1.5 µm, n = 20) wide, composed of numerous, filiform, hyaline, aseptate or separate, rarely branched, guttulate, smooth-walled pseudoparaphyses. ***Asci*** 40–70 × 6–9 µm ($\bar{x}$ = 53 × 8 µm, n = 30), 5–8-spored, bitunicate, fissitunicate, clavate, short cylindrical pedicellate with a swollen base, apically rounded, with a minute ocular chamber. ***Ascospores*** 10–13 × 4–6 µm ($\bar{x}$ = 12 × 5 µm, n = 50), 1–2-seriate, partially overlapping, fusoid to ellipsoid, tapering towards the blunt ends, or blunt at both ends, guttulate, olivaceous to yellowish-brown when young, aseptate or 1-septate; deeply constricted at septa, becoming 3-septate, brown to dark brown when mature, without appendages. **Asexual morph:** Undetermined.

Culture characteristics. Ascospores germinated on PDA within 24 h, and germ tubes produced from basal cell. Colonies growing on PDA reached 17–18 mm in diameter after three weeks at 25 °C in dark, white in the whole colony from above, circular, edge entire, margin well-defined; in reverse, off-white to grayish brown, no pigmentation on PDA.

Material examined. China • Yunnan Province, Xishuangbanna Dai Autonomous Prefecture, Mengla County, Xishuangbanna Tropical Botanical Garden Chinese Academy of Sciences. 21°56'1"N, 101°25'33"E, elevation 505 m, on dead branches of medicinal plant *Citrus medica* L. (Rutaceae), 10 November 2022, H.Z. Du, S655 (HKAS 131311, holotype; HUEST 23.0200, isotype); ex-holotype living culture CGMCC 3.25626; ex-isotype living culture UESTCC 23.0200.

Notes. *Nigrograna longiorostiolata* shares similar morphology with *N. magnoliae* (holotype, MFLU 20–0092) and *N. kunmingensis* (holotype, ZHKU 22-0141) in having immersed, globose to subglobose ascomata, bitunicate and clavate asci, fusoid to ellipsoid, 3-septate mature ascospores. However, the ascomata size of *N. longiorostiolata* (222–293 × 144–486 µm) is larger than *N. magnoliae* (200–300 × 100–150 µm) (Wanasinghe et al. 2020) and smaller than *N. kunmingensis* (300–500 × 390–450 µm) (Liu et al. 2024). The phylogenetic result (Fig. 1) showed that *N. longiorostiolata* (CGMCC 3.25626 and UESTCC 23.0200) can be recognized as a distinct phylogenetic species with high bootstrap support (100% MLBS/1.00 BIPP). Additionally, *N. longiorostiolata* (ex-type strain, CGMCC 3.25626) can be distinguished from *N. magnoliae* (ex-type strain, MFLUCC 20-0020) by 26/471 bp (5.5%, 2 gaps) in ITS, 14/831 bp (1.7%, without gaps) in LSU, 30/855 bp (3.5%, 3 gaps) in *tef1-α* and 96/1042

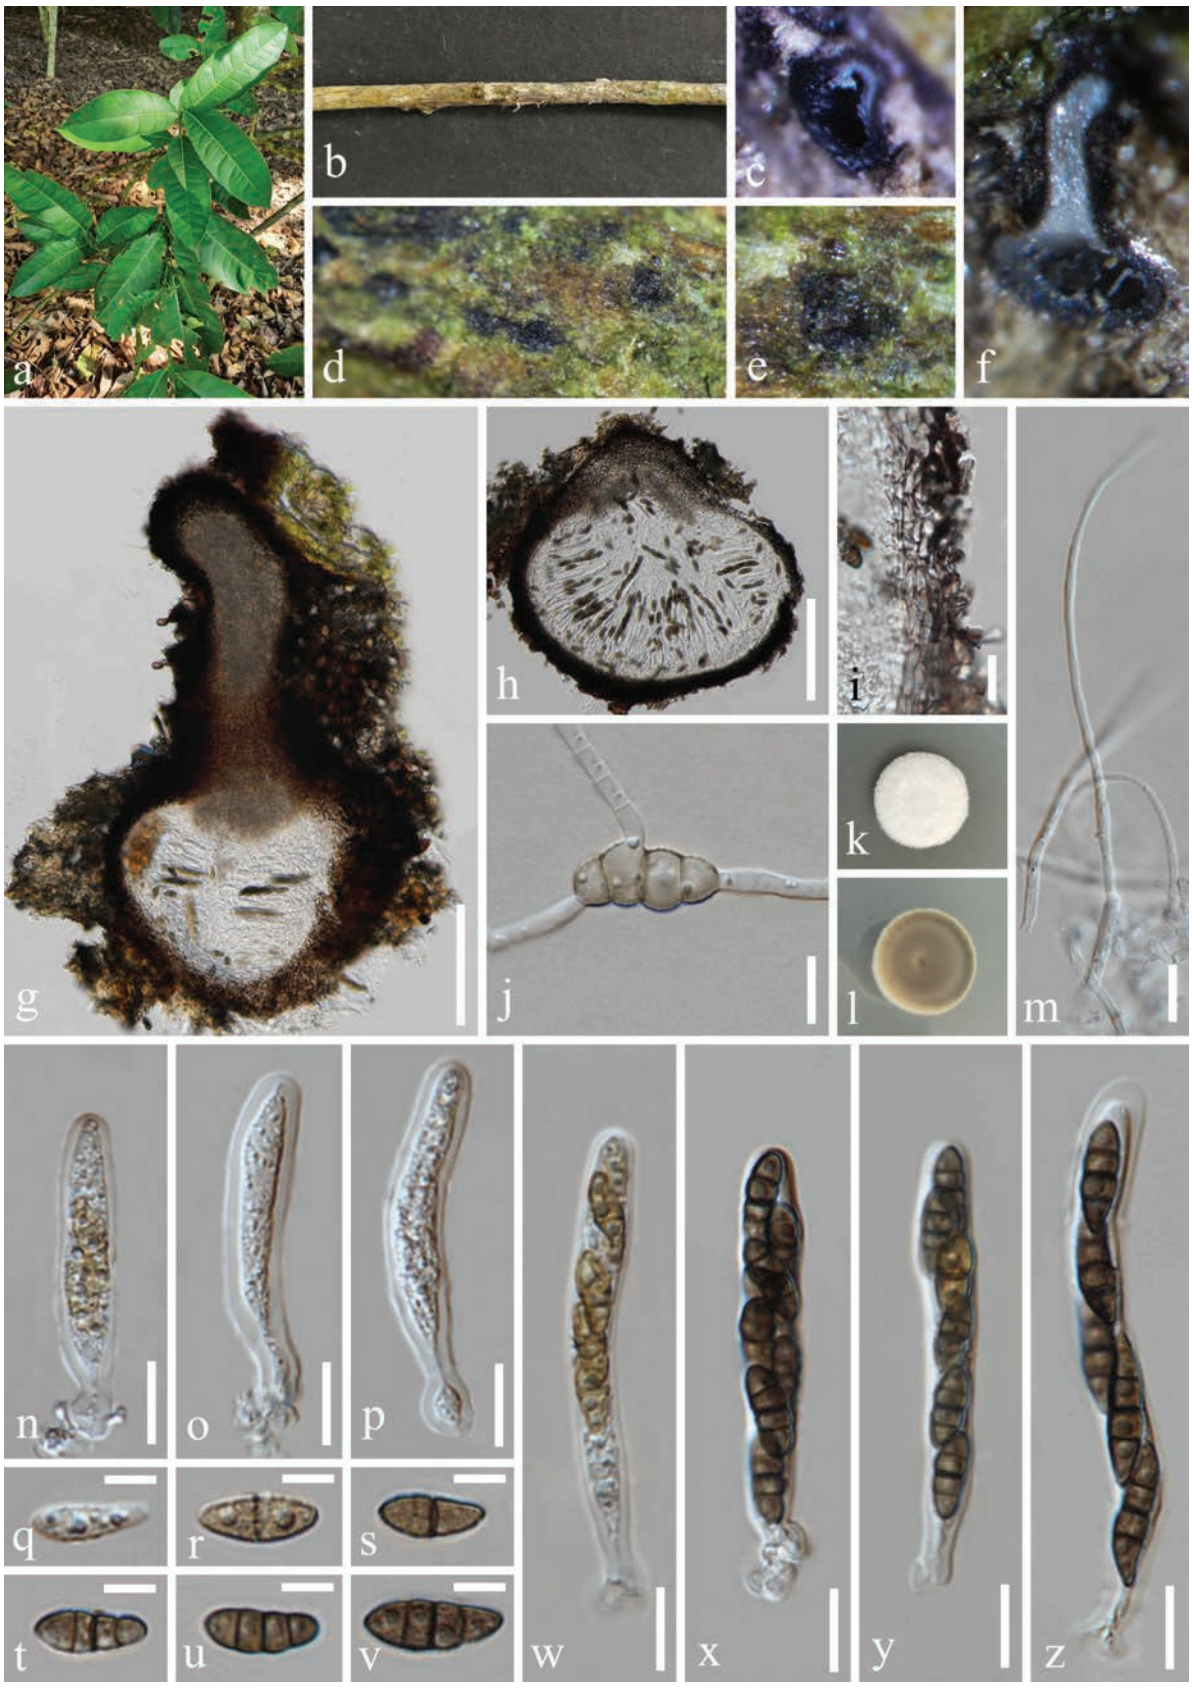

Figure 3. *Nigrograna longiorostiolata* (HKAS 131311, holotype) **a** host *Citrus medica* **b** branch of *Citrus medica* **c–f** appearance of ascomata on host surface **g, h** vertical section through ascoma **i** peridium **j** germinated ascospore **k, l** colony on PDA, above (**k**) and below (**l**) **m** hamathecium **n–p, w–z** asci **q–v** ascospores. Scale bars: 100 µm (**g, h**); 10 µm (**i, j, m–p, w–z**); 5 µm (**q–v**).

bp (9.2%, without gaps) in *rpb2* differences, and differs from *N. kunmingensis* (ex-type strain, ZHKUCC 22-0242) with 70/823 bp (8.5%, 21 gaps) of ITS, 14/844 bp (1.7%, without gaps) of LSU and 30/855 bp (3.5%, 3 gaps) of *tef1-α* differences. Therefore, *N. longiorostiolata* associated with *Citrus medica* is a phylogenetically distinct specie and introduced as a new species.

***Nigrograna acericola* W.L. Li & Jian K. Liu, Mycosphere, 14(1): 1496–1500 (2023)**

MycoBank No: 849155

Fig. 4

Description. ***Saprobic*** on dead branches of *Gymnosporia acuminata* (Celastraceae). **Sexual morph:** ***Ascomata*** 524–647 × 341–475 µm ($\bar{x}$ = 586 × 424 µm, n = 20), solitary, scattered, immersed, ostiolar necks visible on the host surface or erumpent, subglobose to ellipsoid, coriaceous, brown to dark brown, with an ostiole. ***Ostioles*** 86–138 µm long, 64–119 µm wide ($\bar{x}$ = 113 × 96 µm, n = 20), mostly central, some eccentric, with a crest-like apex, central, filled with hyaline periphyses. ***Peridium*** 15–58 µm ($\bar{x}$ = 40 µm, n = 20) µm wide, composed of 4–5 layers of flattened, brown to dark brown, thin-walled cells of ***textura angularis***, the inner layer is dense, the outer layer sparse. ***Hamathecium*** 1.5–3 µm ($\bar{x}$ = 2 µm, n = 20) wide, composed of numerous, filamentous, hyaline, unbranched pseudoparaphyses. ***Asci*** 70–87 × 12–14 µm ($\bar{x}$ = 77 × 13 µm, n = 30), 8-spored, bitunicate, fissitunicate, cylindrical to clavate, short pedicellate, apically rounded, with a minute ocular chamber. ***Ascospores*** 16–19 × 5–7 µm ($\bar{x}$ = 17 × 6 µm, n = 50), 1–2-seriate, biseriate or partially overlapping, fusoid to ellipsoid, with obtuse ends, tapering towards the ends, guttulate, smooth-walled, 1-septate, subhyaline to yellowish-brown when young; becoming 3-septate, slightly constricted at the middle septum, brown to dark brown when mature, without appendages. **Asexual morph:** Undetermined.

Culture characteristics. Ascospores germinated on PDA within 24 h, and germ tubes produced from basal cell. Colonies growing on PDA reached 38–40 mm in diameter after three weeks at 25 °C in dark, white in the whole colony from above, circular, edge entire, margin well-defined; in reverse, light brown in the center, olive gray at the margin, no pigmentation on PDA.

Material examined. China • Yunnan Province, Xishuangbanna Dai Autonomous Prefecture, Mengla County, Xishuangbanna Tropical Botanical Garden Chinese Academy of Sciences. 21°55'54"N, 101°15'16"E, elevation 511 m, on dead branches of medicinal plant *Gymnosporia acuminata* Hook. f. Nigrograna camelliae **Y.H. Lu, H.Z. Du & Jian K. Liu, sp. nov.**
MycoBank No: 854178
Fig. 5

Etymology. The epithet '*camelliae*' refers to the host genus *Camelliae* from which the fungus was originally isolated.

Holotype. HKAS 131310

Description. ***Saprobic*** on dead branches of *Camellia sinensis* (Theaceae). **Sexual morph:** ***Ascomata*** 137–270 µm wide, 208–324 µm high ($\bar{x}$ = 212 × 265 µm, n = 20), solitary, scattered, immersed, black spots on the host substrate, globose to subglobose, sometimes obpyriform, ostiolate, hairs of ascomata 2–3 µm wide, slightly brown, septate. ***Ostioles*** 65–138 µm long, 32–60 µm wide ($\bar{x}$ = 100 × 45 µm, n = 20) mostly central, some eccentric, with a crest-like apex. ***Peridium*** 19–30 µm ($\bar{x}$ = 23 µm, n = 20) wide, composed of 2–3 layers, comprising reddish brown to dark brown pigmented cells. ***Hamathecium*** 2–3 µm ($\bar{x}$ = 2.5 µm, n = 20) wide, composed of numerous, filiform, hyaline, aseptate or separate, filamentous, smooth-walled pseudoparaphyses. ***Asci*** 70–108 × 9–11 µm ($\bar{x}$ = 80 × 10 µm, n = 30), 8-spored, bitunicate, fissitunicate, clavate to cylindric-clavate, short stalked, some with a swollen base, apically rounded, with a small ocular chamber. ***Ascospores*** 13–16 × 4–6 µm ($\bar{x}$ = 15 × 5 µm, n = 50), overlapping uni- to bi-seriately arranged, fusoid to ellipsoid, tapering towards the blunt ends, or blunt at both ends, straight or slightly curved, 1-septate, constricted, with obviously guttulate, hyaline to slightly brown when immature, pale brown to brown when mature, without appendages. **Asexual morph:** Undetermined.

Culture characteristics. Ascospores germinated on PDA within 24 h, and germ tubes produced from basal cell. Colonies growing on PDA reached 35–36 mm in diameter after three weeks at 25 °C in dark, white in the whole colony and slightly bright yellow in the center from above, circular, edge entire, margin well-defined; in reverse, yellowish brown in the center, slightly brown at the margin and presented an outer ring, no pigmentation on PDA.

Material examined. China • Sichuan Province, Yaan City, Mingshan County, Mengding Mountain. 30°4'32"N, 103°2'23"E, elevation 1,200 m, on dead branches of medicinal plant *Camellia sinensis* (L.) O. Ktze. (Theaceae), 16 July 2023, Y. H. Lu & X. D. Liang, MD03A (HKAS 131310, holotype; HUEST 23.0197, isotype); ex-holotype living culture CGMCC 3.25625; ex-isotype living culture UESTCC 23.0197.

Notes. *Nigrograna camelliae* is phylogenetically close to *N. coffeae* and represents as a distinct lineage (Fig. 1). Additionally, the nucleotide base pair comparison between *N. camelliae* (ex-type strain, CGMCC 3.25625) and *N. coffeae* (ex-type strain, ZHKUCC 22-0210) revealed 15/514 bp (2.9%, 1 gap) of ITS, 11/698 bp (1.6%, without gaps) of LSU, 74/739 bp (10.0% without gaps) of *rpb2* and 28/914 bp (3.1%, without gaps) of *tef1-α* differences. Furthermore, *N. camelliae* morphologically resembles *N. coffeae* in having immersed ascomata, clavate and short pedicellate asci, pale brown to brown and septate ascospores with obviously guttulate (Lu et al. 2022). However, *N. camelliae* differs from *N. coffeae* in having ascomata with hairs and ostioles, solitary or scattered in the substrate. Additionally, they can be distinguished in having larger ascomata (208–324 × 137–270 µm vs. 140–200 × 90–140 µm) and asci (70–108 × 9–11 µm vs. 50–70 × 7–11 µm). Therefore, *N. camelliae* is introduced as a new species with the justification of phylogenetic and morphological evidence.

MycoBank No: 849157
Fig. 6

= *Nigrograna trachycarpi*, MycoKeys 100: 141 (2023).

Description. ***Saprobic*** on dead branches of *Ardisia crenata* (Primulaceae). **Sexual morph:** ***Ascomata*** 190–334 µm wide, 303–406 µm high ($\bar{x}$ = 233 × 370 µm, n = 20), solitary or gregarious, scattered, immersed, often lying parallelly or obliquely to the bark or host surface, with a cylindrical ostiolar neck, coriaceous, obpyriform, brown to dark brown. ***Ostioles*** central or eccentric, filled with hyaline periphyses. ***Peridium*** 16.5–25 µm ($\bar{x}$ = 21 µm, n = 20) wide, consisting 4–6 layers of brown-walled cells of ***textura angularis***. ***Hamathecium*** 1–2 µm ($\bar{x}$ = 1.5 µm, n = 20) wide, aseptate or separate, composed of numerous, filiform, smooth-walled pseudoparaphyses. ***Asci*** 62–127 × 9–12 µm ($\bar{x}$ = 82 × 10 µm, n = 30), 8-spored, bitunicate, fissitunicate, clavate to long cylindric-clavate, with a short pedicel, apically rounded, with a smaller ocular chamber. ***Ascospores*** 14–17 × 4–6 µm ($\bar{x}$ = 15 × 5 µm, n = 50), 1–2-seriate, fusoid to ellipsoid, apical cell mostly obtuse, straight or slightly curved, guttulate, smooth-walled, 3-septate, constricted at the septa, pale brown to yellow-brown when young, brown to chocolate-brown at maturation, without appendages. **Asexual morph:** Undetermined.

Culture characteristics. Ascospores germinated on PDA within 24 h, and germ tubes produced from basal cell. Colonies growing on PDA reached 22–23 mm in diameter after three weeks at 25 °C in dark. Colonies from above, circular, margin entire, dense, surface smooth, velvety appearance, white in the center, presented a pale greenish furrowed ring, white to cream at the margin; in reverse, brown in the central point, brown-gray in the middle, white to pale brownish at the edge, no pigmentation on PDA.

Material examined. China • Yunnan Province, Xishuangbanna Dai Autonomous Prefecture, Mengla County, Xishuangbanna Tropical Botanical Garden Chinese Academy of Sciences. 21°55'49"N, 101°15'19"E, elevation 516 m, on dead branches of medicinal plant *Ardisia crenata* Sims (Primulaceae), 10 November 2022, H.Z. Du, D01 (HUEST 23.0209), living culture UESTCC 23.0209; • ibid., Sichuan Province, Chengdu City, Pujiang County, 30°11'42"N, 103°22'21"E, elevation 630 m, on dead branches of *Camellia sinensis* (L.) O. Ktze. (Theaceae), 5 October 2022, Y.H. Lu & Y. Xiao, A11 (HUEST 23.0193), living culture UESTCC 23.0193.

Notes. *Nigrograna oleae* was introduced by Li et al. (2023) from *Olea europaea* and *N. trachycarpi* was described by Hu et al. (2023) from *Trachycarpus* sp. in China. In this study, multi-locus phylogeny indicated that our two isolates clustered together with *N. oleae* (ex-type strain, CGMCC 3.24423) and *N. trachycarpi* (ex-type strain, GMB0499) by strong support (100% MLBS/1.00 BIPP) (Fig. 1). In addition, the nucleotide base pair comparison of ex-type strain between *N. oleae* (CGMCC 3.24423) and *N. trachycarpi* (GMB0499) was identical by 421/421 bp (100%) of ITS, and 466/466 bp (100%) of *tef1-α*. Additionally, our newly collected specimens share similar morphology with *N. oleae* and *N. trachycarpi*. Therefore, we identify our collections as *N. oleae* and propose the synonymy of *N. trachycarpi* under *N. oleae* based on morphology and phylogeny. The new host records for *N. oleae* from medicinal plants *Ardisia crenata* and *Camellia sinensis* are reported in this study.

Figure 6. *Nigrograna oleae* (HUEST 23.0209, new host record) **a** host *Ardisia crenata* **b** branch of *Ardisia crenata* **c–f** appearance of ascomata on host surface **g, h** vertical section through ascoma **i** peridium **j–l** asci **m–q** ascospores **r, s** colony on PDA, above (**r**) and below (**s**). Scale bars: 100 μm (**g, h**); 20 μm (**i–l**); 10 μm (**m–q**).

***Nigrograna thymi* Mapook, Camporesi & K.D. Hyde, Fungal Diversity, 87: 68–70 (2017)**
MycoBank No: 552958
Fig. 7

Description. ***Saprobic*** on dead branches of *Huangtcia renifolia* (Fabaceae). **Sexual morph:** ***Ascomata*** 292–359 µm wide, 166–278 µm high ($\bar{x}$ = 327 × 218 µm, n = 20), solitary or scattered, immersed or semi-immersed to slightly erumpent through host tissue, coriaceous, globose to subglobose, brown to dark brown, hairs of ascomata 2–3 µm wide, brown, septate, branched. ***Ostiole*** inconspicuous, without papillate. ***Peridium*** 15–44 µm ($\bar{x}$ = 29.5 µm, n = 20) wide, 5–6 layers, comprising dark brown cells of ***textura angularis***. ***Hamathecium*** comprising 1–3 µm ($\bar{x}$ = 2 µm, n = 20) wide, cylindrical to filiform, septate, branched, smooth-walled pseudoparaphyses. ***Asci*** 43–86 × 7–9 µm ($\bar{x}$ = 66 × 8 µm, n = 30), 8-spored, bitunicate, cylindrical to broadly filiform, with small ocular chamber. ***Ascospores*** 11–15 × 4–6 µm ($\bar{x}$ = 13 × 4.5 µm, n = 50), 1–2-seriate, overlapping, broadly fusiform to inequilateral, widest at the middle cell, guttulate, smooth-walled, aseptate or 1-septate, hyaline when immature, becoming 3-septate, slightly constricted at the septum, pale brown to brown at maturity, without appendages. **Asexual morph:** Undetermined.

Culture characteristics. Ascospores germinated on PDA within 24 h, and germ tubes produced from basal cell. Colonies growing on PDA reached 20 mm in diameter after three weeks at 25 °C in dark. Colonies from above, white in the whole colony and raised in the center, circular, edge entire, margin well-defined; in reverse, grayish-green in the center, white to pale green ring at the margin, no pigmentation on PDA.

Material examined. O. Ktze. (Theaceae), 18 July 2023, Y.H. Lu & X.D. Liang, EM03 (HUEST 23.0194), living culture UESTCC 23.0194.

Notes. *Nigrograna thymi* was introduced by Hyde et al. (2017) from *Thymus oenipontanus* in Italy. Our collections are identical to *N. thymi* based on morphology and phylogeny (Fig. 1). We reported it as new host records from medicinal plants *Huangtcia renifolia* and *Camellia sinensis* in China.

***Nigrograna neriicola* Y.H. Lu, H.Z. Du & Jian K. Liu, sp. nov.**
MycoBank No: 854179
Fig. 8

Etymology. The epithet '*neriicola*' refers to the host genus *Nerium* from which the fungus was originally isolated.

Holotype. HKAS 131313.

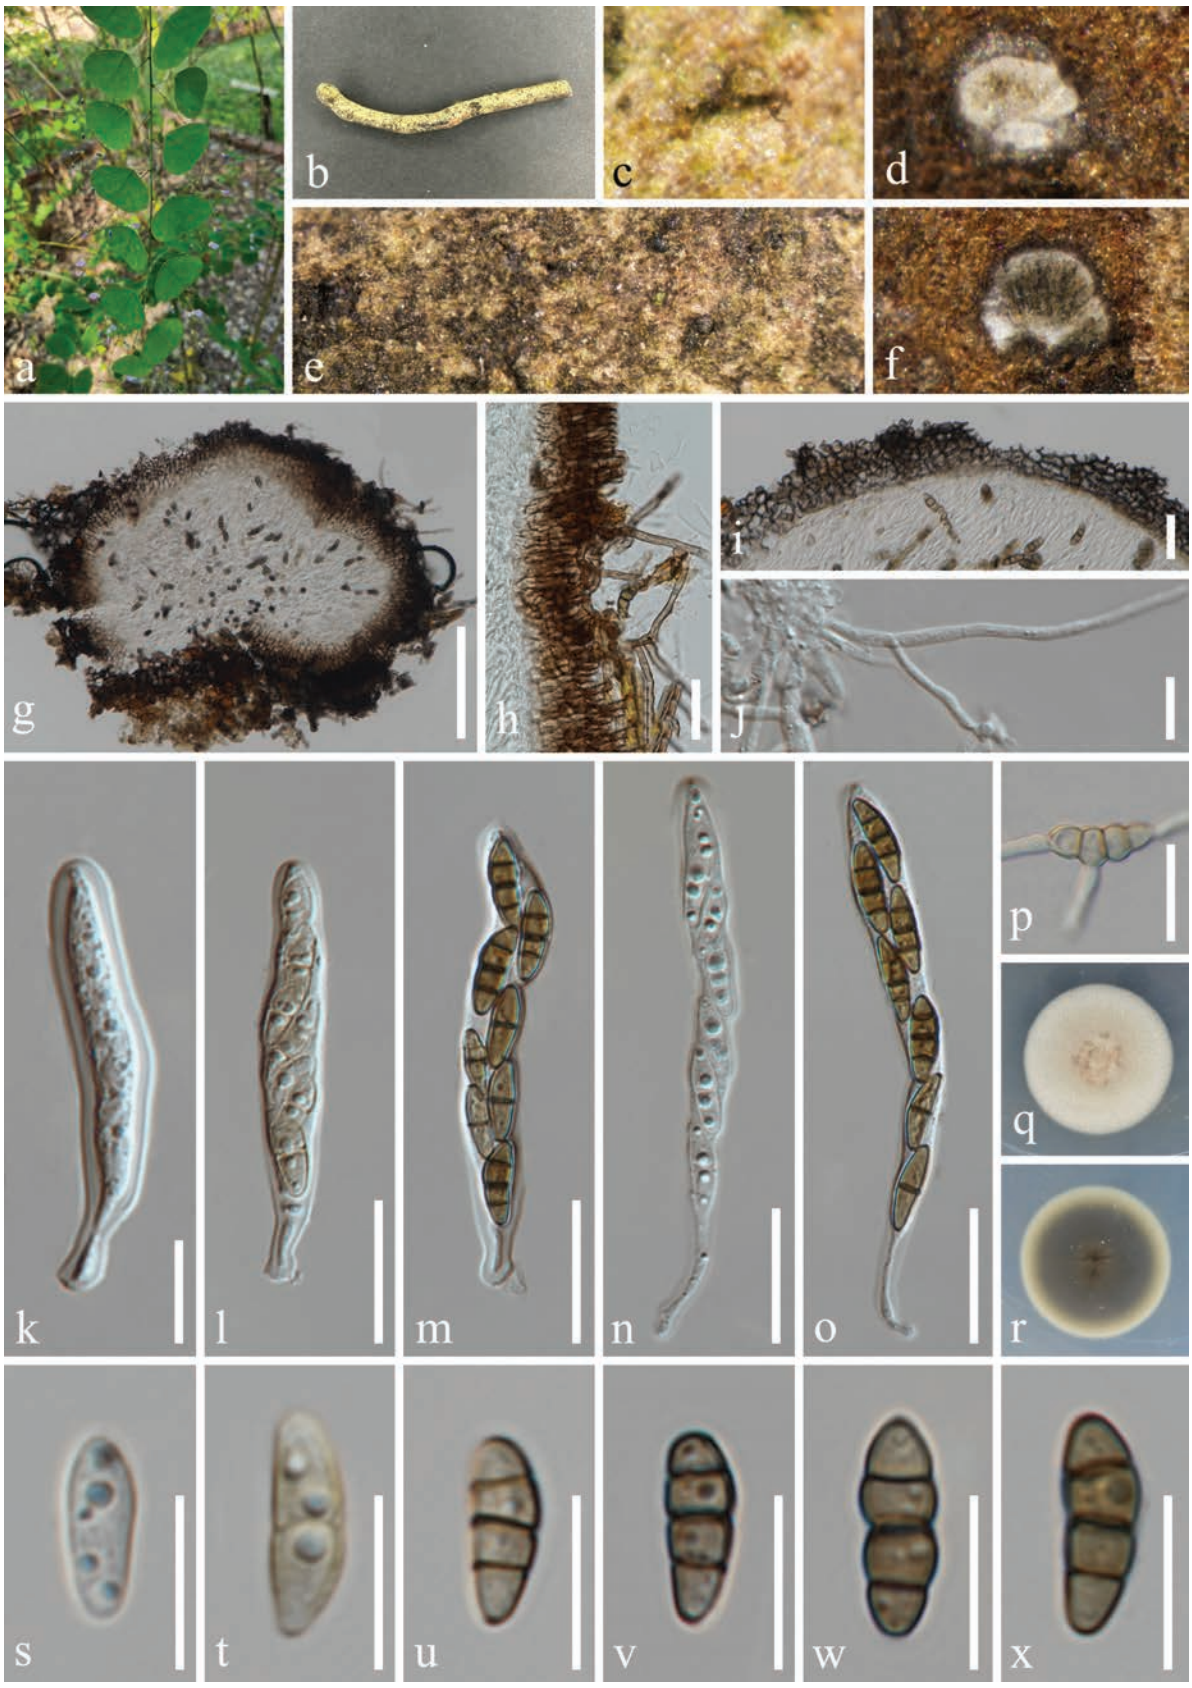

Figure 7. *Nigrograna thymi* (HUEST 23.0210, new host record) **a** host *Huangtcia renifolia* **b** branch of *Huangtcia renifolia* **c–f** appearance of ascomata on host surface **g** vertical section through ascoma **h** hairs on ascomata **i** peridium **j** hamathecium **k–o** asci **p** germinated ascospore **q, r** colony on PDA, above (**q**) and below (**r**) **s–x** ascospores. Scale bars: 100 µm (**g**); 20 µm (**h, i, l–p**); 10 µm (**j, k, s–x**).

Description. ***Saprobic*** on dead branches of *Nerium oleander* (Apocynaceae). **Sexual morph:** ***Ascomata*** 138–231 µm wide, 156–251 µm high ($\bar{x}$ = 182 × 202 µm, n = 20), mostly gregarious, sometimes solitary, scattered, immersed to semi-immersed, appearing as black irregular protrusions and cracks, globose to subglobose, sometimes obpyriform, dark brown to black, with an ostiole. ***Ostioles*** 32–54 µm long, 14–34 µm wide ($\bar{x}$ = 45 × 25 µm, n = 20) mostly central, some eccentric, with a crest-like apex. ***Peridium*** 16–61 µm ($\bar{x}$ = 32 µm, n = 20) wide, multi-layered, reticulate structure, comprising dark brown to reddish brown pigmented cells of ***textura angularis***. ***Hamathecium*** 1–2.5 µm wide ($\bar{x}$ = 2 µm, n = 20), composed of numerous, filiform, hyaline, aseptate or separate, rarely branched, filamentous, smooth-walled pseudoparaphyses. ***Asci*** 35–80 × 7–10 µm ($\bar{x}$ = 56 × 8.5 µm, n = 30), 8-spored, bitunicate, fissitunicate, clavate to cylindric-clavate, short stalked, some with club-shape pedicel, apically rounded with a small ocular chamber. ***Ascospores*** 12–21(–31) × 3.5–5 µm ($\bar{x}$ = 16 × 4 µm, n = 50), uni- to bi-seriately arranged, partially overlapping, fusoid to ellipsoid, tapering towards the blunt ends, or blunt at both ends, straight or slightly curved, guttulate, smooth-walled, 1-septate, subhyaline to slightly brown when young; becoming 3-septate, yellowish-brown to dark brown when mature, deeply constricted at septa, without appendages. **Asexual morph:** Undetermined.

Culture characteristics. Ascospores germinated on PDA within 24 h, and germ tubes produced from basal cell. Colonies growing on PDA reached 33–35 mm in diameter after one month at 25 °C in dark, slightly brown in the whole colony and raised in the central point from above, circular, edge entire, margin well-defined, aerial mycelia dense; in reverse, black-brown in the center, slightly brown ring at the margin, no pigmentation on PDA.

Material examined. China • Yunnan Province, Xishuangbanna Dai Autonomous Prefecture, Mengla County, Xishuangbanna Tropical Botanical Garden Chinese Academy of Sciences. 21°55'52"N, 101°15'29"E, elevation 505 m, on dead branches of medicinal plant *Nerium oleander* L. (Apocynaceae), 10 November 2022, H.Z. Du, D04 (HKAS 131313, holotype); ex-holotype living culture CGMCC 3.25624; • ibid., Sichuan Province, Chengdu City, Pujiang County. 30°11'40"N, 103°22'25"E, elevation 600 m, on dead branches of *Camellia sinensis* (L.) O. Ktze. (Theaceae), 5 October 2022, Y.H. Lu & Y. Xiao, M03 (HUEST 23.0195, paratype); ex-paratype living culture UESTCC 23.0195.

Notes. *Nigrograna neriicola* (CGMCC 3.25624 and UESTCC 23.0195) has close phylogenetic relationships with *N. schinifolii* (GMB0498 and GMB0504) but formed a distinct lineage (Fig. 1). Morphologically, the ascomata of *N. neriicola* differs from *N. schinifolii* in having black irregular protrusions and cracks, mostly gregarious, and ascospores that are slightly larger than *N. schinifolii* (12–21 × 3.5–5 µm vs. 10–14 × 2.8–4 µm) (Hu et al. 2023). Additionally, the nucleotide base pair comparison between *N. neriicola* (ex-type strain, CGMCC 3.25624) and *N. schinifolii* (ex-type strain, GMB0498) revealed no significant differences by 375/377 bp (99.5%, 1 gap) of ITS and 507/511 bp (99.2%, without gaps) of *tef1-α*. However, for *tef1-α* gene, the length of the two *N. schinifolii* strains (GMB0498 and GMB0504) is only 511 bp. The problem of low similarity occurred after the blastn search without a corresponding sequence in the same genus for alignment. Therefore, *N. neriicola* is introduced as a new species with the morpho-molecular data analysis.

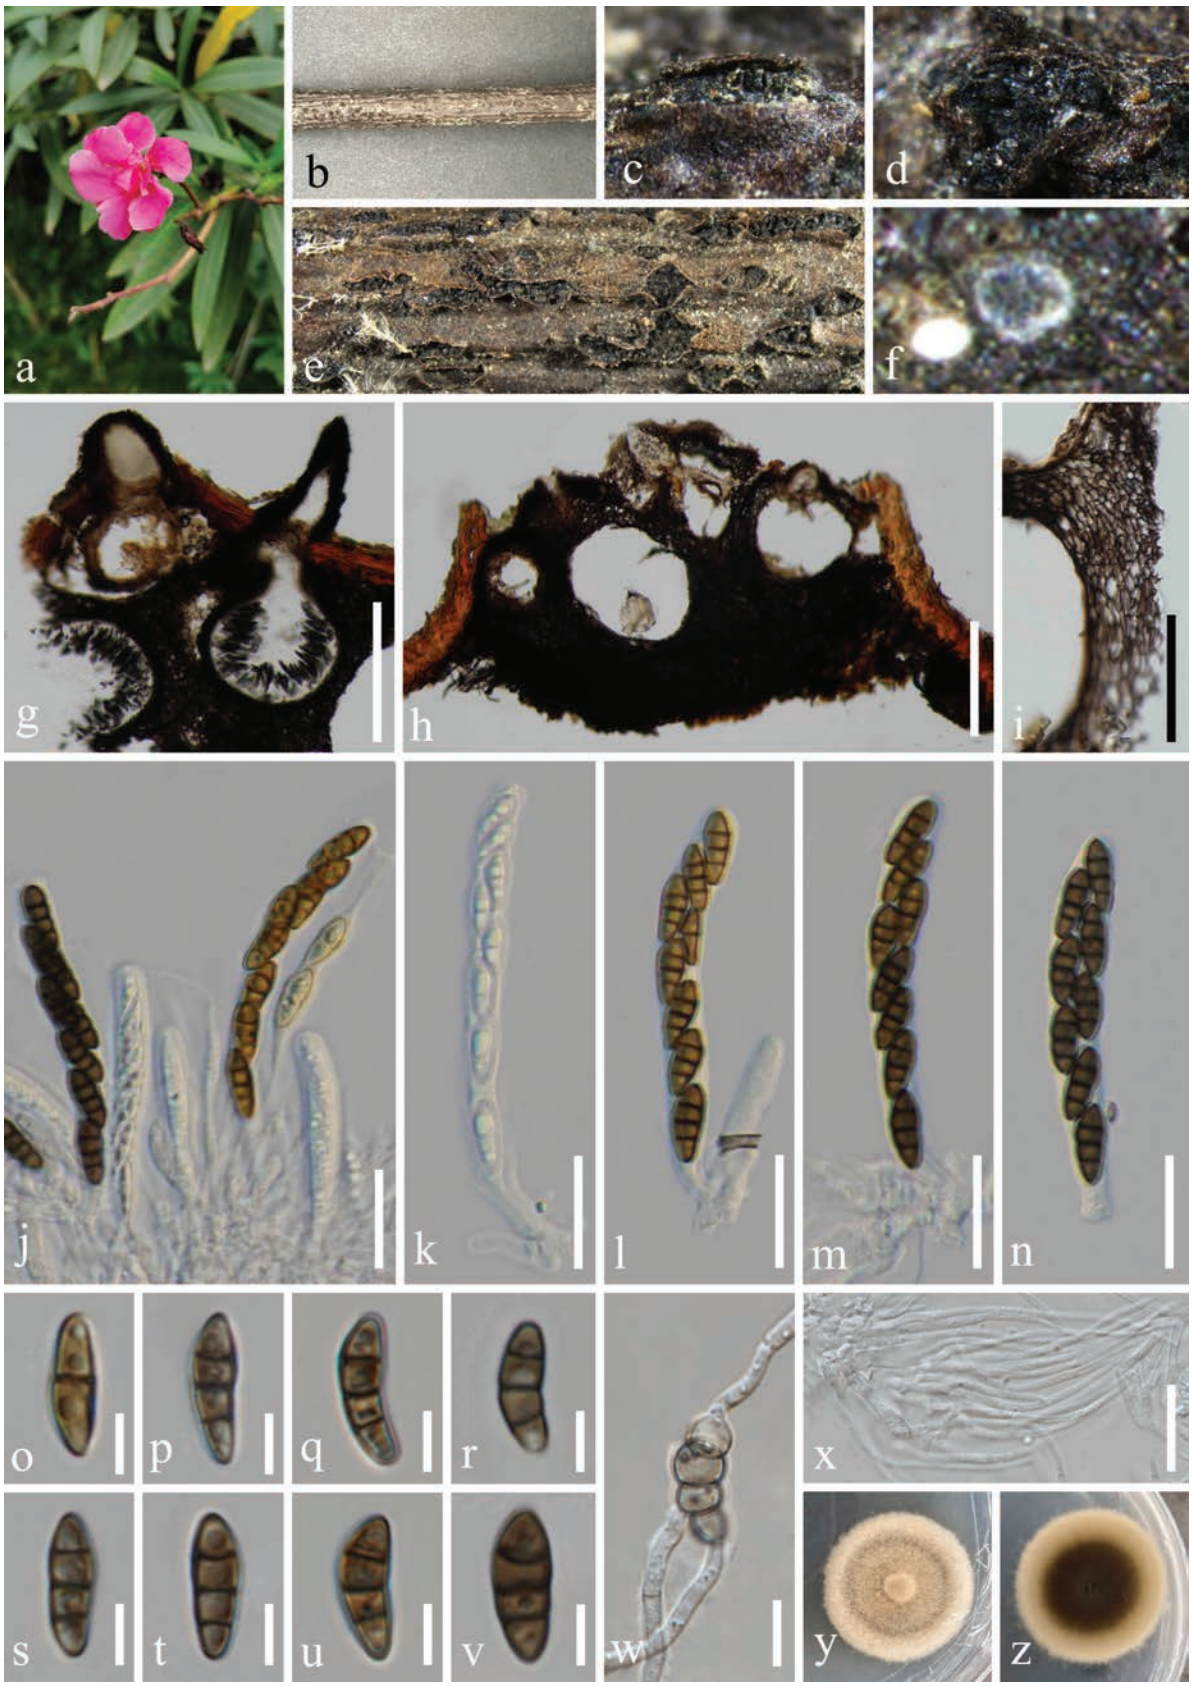

Figure 8. *Nigrograna neriicola* (HKAS 131313, holotype) **a** host *Nerium oleander* **b** branch of *Nerium oleander* **c–f** appearance of ascomata on host surface **g, h** vertical section through ascoma **i** peridium **j–n** asci **o–v** ascospores **w** germinated ascospore **x** hamathecium **y, z** colony on PDA, above (**y**) and below (**z**). Scale bars: 200 µm (**g, h**); 100 µm (**i**); 20 µm (**j–n, x**); 5 µm (**o–v**); 10 µm (**w**).

***Nigrograna guttulata* Y.H. Lu, H.Z. Du & Jian K. Liu, sp. nov.**
MycoBank No: 854180
Fig. 9

Etymology. The epithet '*guttulata*' refers to the guttulate ascospores.

Holotype. HKAS 131992.

Description. ***Saprobic*** on dead branches of *Camellia sinensis* (Theaceae). **Sexual morph:** ***Ascomata*** 182–283 µm wide, 106–276 µm high ($\bar{x}$ = 241 × 183 µm, n = 20), solitary, immersed, ostiolar necks visible on the host surface or erumpent, triangular, globose to subglobose, sometimes obpyriform, coriaceous, ostiolate, dark brown to black. ***Ostioles*** 35–61 µm long, 15–30 µm wide ($\bar{x}$ = 47 × 22 µm, n = 20) mostly central, some eccentric, filled with hyaline periphyses. ***Peridium*** 15–37 µm ($\bar{x}$ = 25 µm, n = 20) wide, multi-layered, reticulate structure, comprising dark brown to reddish brown pigmented cells of ***textura angularis***. ***Hamathecium*** 1–2.5 µm wide ($\bar{x}$ = 2 µm, n = 20), composed of numerous, filiform, hyaline, aseptate or separate, some branched, filamentous, smooth-walled pseudoparaphyses. ***Asci*** 35–70 × 7–12 µm ($\bar{x}$ = 48 × 8.5 µm, n = 30), 8-spored, bitunicate, fissitunicate, clavate to cylindric-clavate, short stalked, some with club-shape pedicel, apically rounded, with small ocular chamber. ***Ascospores*** 10–13 × 3–5 µm ($\bar{x}$ = 12 × 4 µm, n = 50), 1–2-seriate, overlapping, fusoid to ellipsoid, tapering towards the blunt ends, or blunt at both ends, straight or slightly curved, guttulate, smooth-walled, subhyaline to slightly brown when young, 1-septate; yellowish-brown to dark brown when mature, becoming 3-septate, deeply constricted at septa, without appendages. **Asexual morph:** Undetermined.

Culture characteristics. Ascospores germinated on PDA within 24 h, and germ tubes produced from basal cell. Colonies growing on PDA reached 35–38 mm in diameter after one month at 25 °C in dark. Colonies from above, white in the whole colony and raised in the central point, circular, margin well-defined, aerial mycelia dense; in reverse, grayish green in the center, white ring at the margin, no pigmentation on PDA.

Material examined. China • Guizhou Province, Guiyang City, Huaxi District, 26°30'40"N, 106°39'30"E, elevation 1,155 m, on dead branches of medicinal plant *Camellia sinensis* (Linnaeus) Kuntze (Theaceae), 2 February 2023, Y.X. Yu & Y.H. Lu, GY15 (HKAS 131992, holotype; HUEST 23.0295, isotype), ex-holotype living culture CGMCC 3.25689; ex-isotype living culture UESTCC 23.0295.

Notes. *Nigrograna peruviensis* was reported by Kolařík et al. (2017) as an endophytic fungus (*Biatriospora peruviensis*) and was synonymized under the genus *Nigrograna* by Kolařík (2018), but with a lack of detailed morphological structures. In this study, our isolates of *N. guttulata* (CGMCC 3.25689 and UESTCC 23.0295) have a close phylogenetic relationship with *N. peruviensis* (Kolařík et al. 2017; Kolařík 2018) based on ITS, LSU, *rpb2*, SSU, and *tef1-α* sequence data, and formed a distinct lineage with absolute bootstrap support (100% MLBS/1.00 BIPP) (Fig. 1). Additionally, *N. guttulata* (ex-type strain, CGMCC 3.25689) can be distinguished from *N. peruviensis* (ex-type strain, CCF 4485) by 8/462 bp (1.7%, 3 gaps) in ITS, 24/1020 bp (2.4%, without gaps) in LSU and 10/618 bp (1.6%, without gaps) in *rpb2* differences. Therefore, the establishment of the new species *N. guttulata* is justified by the phylogenetic evidence.

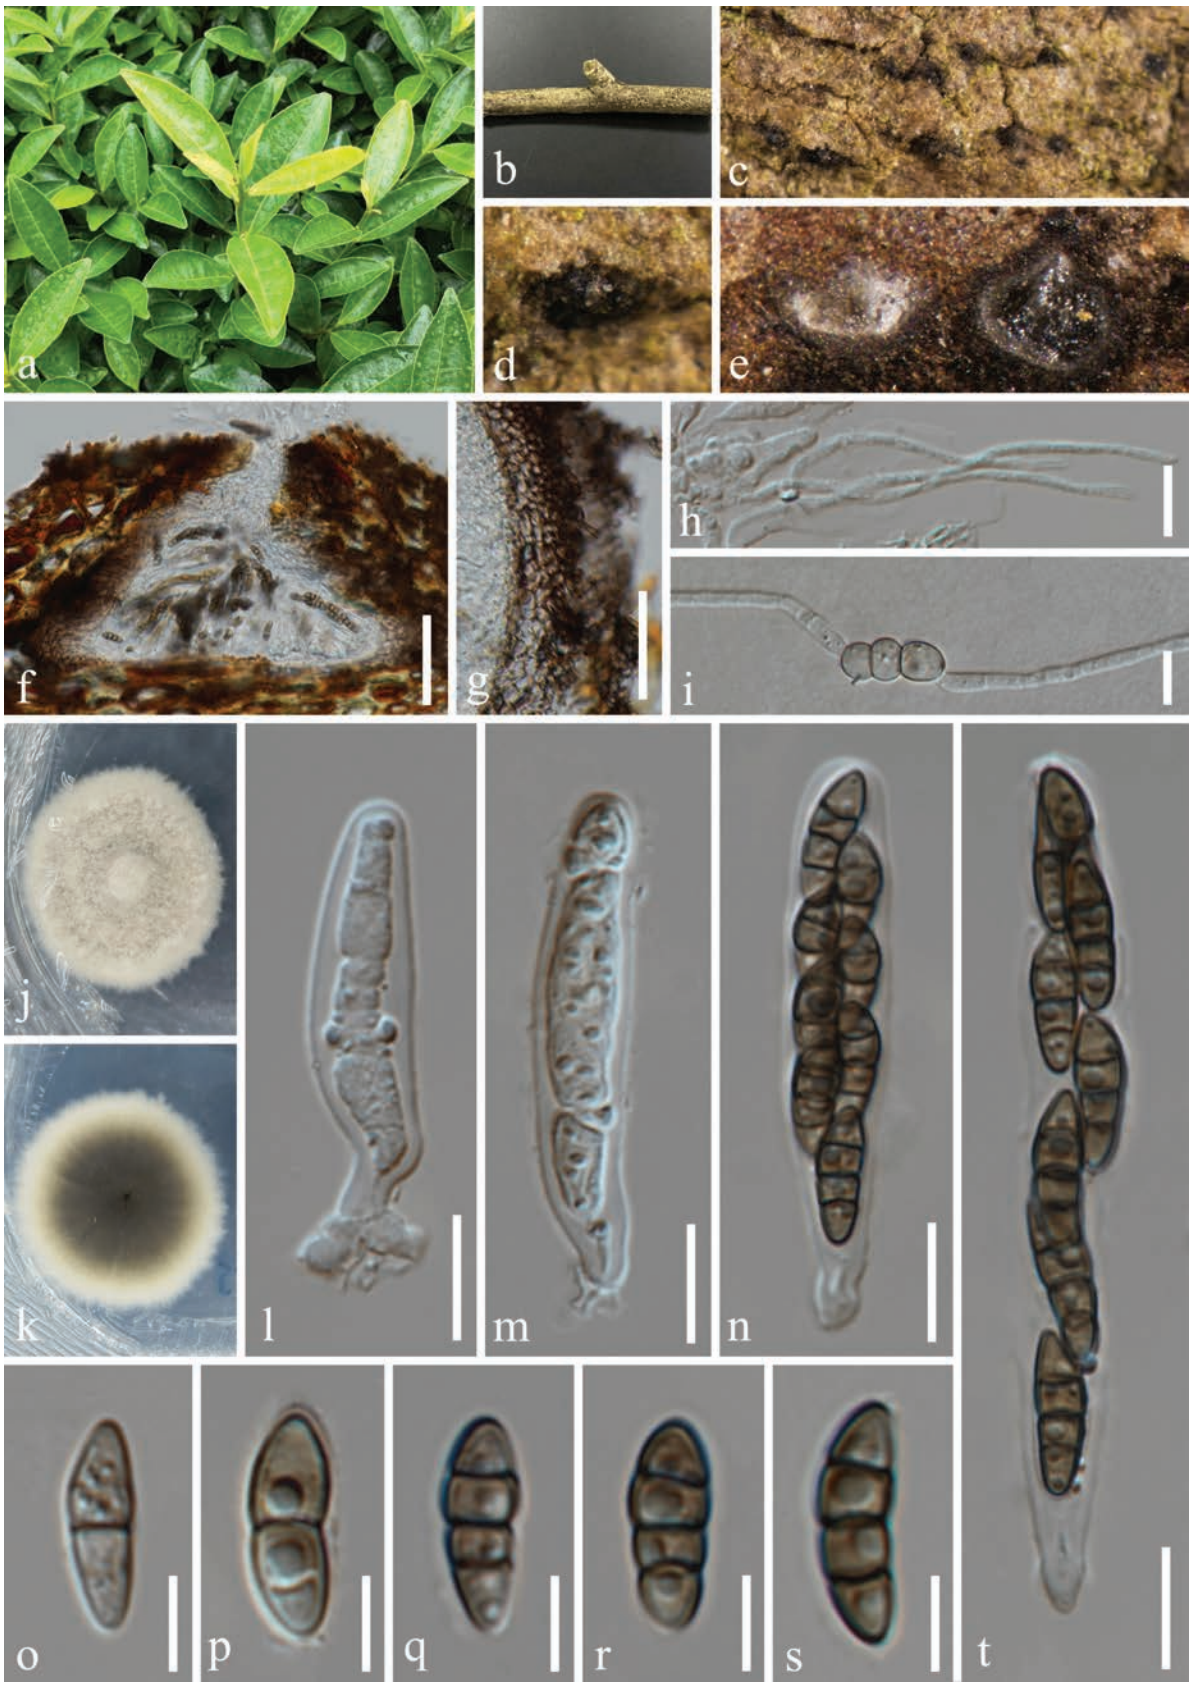

Figure 9. *Nigrograna guttulata* (HKAS 131992, holotype) **a** host *Camellia sinensis* **b** branch of *Camellia sinensis* **c–e** appearance of ascomata on host surface **f** vertical section through ascoma **g** peridium **h** hamathecium **i** germinated ascospore **j, k** colony on PDA, above (**j**) and below (**k**) **l–n, t** asci **o–s** ascospores. Scale bars: 50 µm (**f**); 40 µm (**g**); 10 µm (**h, i, l–n, t**); 5 µm (**o–s**).

Discussion

In this study, eighteen isolates of *Nigrograna* (Nigrograna ceae, Pleosporales, Dothideomycetes) were obtained from medicinal plants in Southwest China (Guizhou, Sichuan and Yunnan Provinces). Based on morphological and culture characteristics, and phylogenetic analyses of combined ITS, LSU, *rpb2*, SSU, and *tef1-α* sequence data, four novel species were identified, namely *Nigrograna camelliae*, *N. guttulata*, *N. longiorostiolata* and *N. neriicola*, Additionally, our known species, namely *N. acericola*, *N. magnoliae*, *N. oleae* and *N. thymi*, were reported from medical plants as new host records. These isolates were associated with terrestrial habitat and collected from medicinal plants in nine plant families, including Apocynaceae, Berberidaceae, Buxaceae, Celastraceae, Eucommiaceae, Fabaceae, Primulaceae, Rutaceae, and Theaceae.

Species within the genus *Nigrograna* exhibit considerable morphological similarity, often complicating species delimitation based solely on morphological traits (Jaklitsch and Voglmayr 2016; Zhang et al. 2020; Lu et al. 2022; Li et al. 2023). As such, molecular data play a critical role in species identification. For example, Jaklitsch and Voglmayr (2016) demonstrated that morphologically similar species, such as *N. coffeae* and *N. camelliae*, can be distinguished phylogenetically. These species sequence divergence across multiple loci, including (15/514 bp, 2.9%, 1 gap), LSU (11/698 bp, 1.6%, without gaps), *rpb2* (74/739 bp, 10.0%, without gaps) and *tef1-α* (28/914 bp, 3.1%, without gaps), highlighting the importance of molecular analysis for accurate taxonomic placement. *Nigrograna* is a worldwide distributed genus, with species reported from Asia (Dayarathne et al. 2020; Mapook et al. 2020; Zhang et al. 2020; Lu et al. 2022; Li et al. 2023), the Americas, and Europe (Jaklitsch and Voglmayr 2016; Hyde et al. 2017; Kolařík et al. 2017; Tibpromma et al. 2017; Kolařík 2018; Zhao et al. 2018; Dayarathne et al. 2020; Wanasinghe et al. 2020). While certain species, such as *N. carollii*, *N. peruviensis* and *N. yasuniana*, have been reported as endophytes on various hosts (Kolařík et al. 2017), the majority of known species are saprotrophs on the bark or corticated twigs and branches of various hardwoods (Jaklitsch and Voglmayr 2016; Mapook et al. 2020; Zhang et al. 2020; Lu et al. 2022; Hu et al. 2023; Li et al. 2023). Reports of *Nigrograna* species on flowers, fruits, leaves, or herbaceous plants are rare, indicating a preference for woody hosts. Consistent with these findings, the isolates in this study were primarily recovered from the branches of medicinal woody plants, such as *Eucommia ulmoides* (Eucommiaceae), *Gymnosporia acuminata* (Celastraceae), and *Mahonia bealei* (Berberidaceae).

It is noteworthy that *Nigrograna magnoliae* was isolated from the bark of *Eucommia ulmoides*, which is a primary medicinal component of the plant. The quality of medicinal plants is closely tied to their clinical efficacy, and the presence of fungal species such as *N. magnoliae* raises important questions about the potential impact of fungal colonization on the medicinal properties of their hosts (Balekundri and Mannur 2020; Rasool et al. 2020; Ali et al. 2021). This finding warrants further investigation to assess whether *N. magnoliae* could affect the quality or bioactive compounds of *E. ulmoides*. In addition to their ecological diversity, certain species within *Nigrograna* have been found to produce bioactive secondary metabolites. For instance, *Nigrograna rubescens* has been reported to produce naphthoquinone compounds, which are known for their broad spectrum

of biological activities (Naysmith et al. 2017; Mack et al. 2024). These metabolites share structural similarities with those found in *N. antibiotica*, which also produces bioactive compounds (Stodůlková et al. 2014). Such findings suggest that members of *Nigrograna* have significant potential for biotechnological applications, particularly in drug discovery. Understanding the relationships between *Nigrograna* species and their medicinal plant hosts, as well as the impact of fungal colonization on the quality of these plants, remains a critical area of research.

In conclusion, this study highlights the diversity of *Nigrograna* species associated with medicinal plants in Southwest China and underscores the importance of integrating morphological and molecular data for accurate species identification. Given the potential ecological and economic implications of *Nigrograna* colonization on medicinal plants, continued research is essential. Detailed taxonomic and ecological studies of *Nigrograna* from medicinal plants will provide valuable insights into the species diversity, host specificity, and potential biotechnological applications of this genus. Ongoing efforts to collect and analyze fresh isolates will further enhance our understanding of the genus and its broader ecological and medicinal significance.

Acknowledgments

Hong-Zhi Du is grateful to Dr. Shaun Pennycook for corrections on the Latin names of the novel taxa. Ning-Guo Liu and Chuan-Gen Lin are thanked for their valuable suggestions on taxonomic identification. Hong-Zhi Du thanks Yong-Xiu Yu, Xiang-Dong Liang and Yue Xiao for their help with sample collections.

Abstract

During a survey of microfungi associated with forest plants, four specimens related to *Kirschsteiniothelia* were collected from decaying wood in Guizhou, Hainan and Yunnan Provinces, China. *Kirschsteiniothelia* species have sexual and asexual forms. They are commonly found as saprophytes on decaying wood and have been reported as disease-causing pathogens in humans as well. In this study, we introduce three novel *Kirschsteiniothelia* species (*K. bulbosapicalis*, *K. dendryphioides* and *K. longirostrata*) and describe a new host record for *K. atra*, based on morphology and multi-gene phylogenetic analyses of a concatenated ITS, LSU and SSU rDNA sequence data. These taxa produced a dendryphiopsis- or sporidesmium-like asexual morph and detailed descriptions and micromorphological illustrations are provided. Furthermore, we provide a checklist for the accepted *Kirschsteiniothelia* species, including detailed host information, habitat preferences, molecular data, existing morphological type, country of origin and corresponding references.

Key words: Checklist, diversity, Dothideomycetes, Kirschsteiniotheliales, one new host record, taxonomy, three new taxa

Introduction

Kirschsteiniothelia was introduced by Hawksworth (1985) and typified by *K. aethiops*, based on morphological observation, linking it to its asexual genus, *Dendryphiopsis* S. Hughes. Later, the type species was reclassified with its asexual morph, *K. atra* (Hyde et al 2011; Wijayawardene et al. 2014). The connection between the sexual morphs of *Kirschsteiniothelia atra* (characterised by cylindrical-clavate, bitunicate, 8-spored or rarely 4-spored asci and ellipsoidal verruculose or smooth ascospores with 1–2 septa, lacking a distinct gelatinous sheath) and the asexual morphs (characterised by macronematous, mononematous and

branched conidiophores, monotretic, terminal or intercalary, cylindrical, doliiform conidiogenous cells and acrogenous, solitary, cylindrical, oblong, septate conidia with obtuse ends) were previously established by Hughes (1978). This connection was confirmed from cultures obtained from fragments of the ascomata, based on morphological examination. Schoch et al. (2006) further confirmed the connection between the sexual and asexual morphs of *Kirschsteiniothelia*, based on both morphology and phylogenetic analysis of SSU, LSU, *tef1-α* and *rpb2*. Boonmee et al. (2012) established a novel family, Kirschsteiniotheliaceae, based on the connection between the sexual and asexual morph of *Kirschsteiniothelia* and multiple gene (LSU, SSU and ITS) phylogeny. Wijayawardene et al. (2014) suggested the use of *Kirschsteiniothelia* as the updated genus to accommodate *Dendryphiopsis* species. As a result, *Dendryphiopsis atra* was re-assigned to *Kirschsteiniothelia* and synonymised with *K. atra*, based on morphological and phylogenetic analyses. In the meantime, Wijayawardene et al. (2014) suggested using *K. atra* to replace *K. aethiops* as the type species of *Kirschsteiniothelia*. This recommendation was supported by later studies (Rossman et al. 2015; Su et al. 2016; Bao et al. 2018; Yang et al. 2023; Jin et al. 2024; Sruthi et al. 2024; Tian et al. 2024). Sruthi et al. (2024) legitimately placed five species from *Dendryphiopsis* under *Kirschsteiniothelia*, namely, *K. arbuscula*, *K. binsarensis*, *K. biseptata*, *K. fascicularis* and *K. goaensis*. *Kirschsteiniothelia* usually exhibits both sexual and asexual morphs (Hawksworth 1985; Boonmee et al. 2012; Hyde et al. 2013; Sun et al. 2021; Xu et al. 2023). The sexual morph of *Kirschsteiniothelia* is characterised by superficial, erumpent, papillate, brown or black and hemi-spherical or subglobose ascomata and cylindrical or clavate, bitunicate, pedicellate asci that are usually 8-spored comprising an ocular apical chamber. The ascospores are ellipsoidal, usually asymmetrical, verruculose or smooth and olivaceous to dark brown, comprising 1–2 septa, with a mucilaginous sheath being occasionally present (Chen et al. 2006; Hyde et al. 2018; Meng et al. 2024). Furthermore, ascospores occasionally display longitudinal or sinuate furrows that are visible from the face view (Hawksworth 1985; Boonmee et al. 2012; Hyde et al. 2013; Mehrabi et al. 2017; Yang et al. 2023).

The asexual morph is further categorised into two types, namely the dendryphiopsis- and sporidesmium-like morphs. The dendryphiopsis-like morph was described by Hughes (1978), who found that the ascomatal fragments of *Kirschsteiniothelia aethiops* (≡ *Amphisphaeria incrustans*) exhibited agar sporulation and morphological traits similar to those of *Dendryphiopsis atra*. This was later supported by Hawksworth (1985). Subsequently, Boonmee et al. (2012) supported the connection between the sexual morph of *Kirschsteiniothelia* and the asexual dendryphiopsis-like morph, based on morphological and phylogenetic analyses. The dendryphiopsis-like morph is characterised by macronematous, septate, cylindrical conidiophores that are irregularly or subscorpioidly branched at the apex. Their conidiogenous cells are mono- to polytretic, integrated, terminal or lateral, doliiform or lageniform. Moreover, the conidia are holoblastic, acrogenous, obclavate, rostrate, obovoid to broadly obovoid, solitary or branched in acropetal chains, exhibiting rounded ends. Taxa exhibiting the dendryphiopsis-like characteristics are *K. atra*, *K. arbuscula*, *K. binsarensis*, *K. biseptata*, *K. dendryphioides*, *K. ebriosa*, *K. emarceis*, *K. fascicularis*, *K. goaensis*, *K. inthanonensis*, *K. lignicola*, *K. longisporum*, *K. nabanheensis*, *K. ramus*, *K. recessa*, *K. saprophytica*, *K. septemseptatum*, *K. shimlaensis*, *K. vinigena* and *K. zizyphifolii* (Hughes 1978; Boonmee et al. 2012; de Farias et al. 2024; Tian et al. 2024; this study).

The sporidesmium-like asexual morph was described by Su et al. (2016), based on morphological and phylogenetic evidence. Despite having different morphological characteristics from other *Kirschsteiniothelia* species, the sporidesmium-like morphs fits into the generic concept of *Kirschsteiniothelia* as they display similar morphologies including unbranched, slender conidiophores that are straight or slightly curved, multi-septate and brown to pale brown, usually truncate at the base and rounded at the apex, producing small conidia. The sporidesmium-like morph is depicted by macronematous, mononematous, unbranched, multi-septate, cylindrical conidiophores, holoblastic, integrated, terminal, determinate, percurrent, cylindrical and caliciform conidiogenous cells and acrogenous, multi-septate, obclavate to obspathulate, rostrate and fusiform conidia that are swollen at the tips or middle of the beak, with or without a conspicuous, gelatinous, hyaline sheath around the tip or middle of the beak. The presence of the sporidesmium-like asexual morph of *Kirschsteiniothelia* was further supported by subsequent research (Sun et al. 2021; Jayawardena et al. 2022; Xu et al. 2023; Yang et al. 2023). Species exhibiting the sporidesmium-like features are *K. acutispora*, *K. agumbensis*, *K. aquatica*, *K. bulbosapicalis*, *K. cangshanensis*, *K. crustacea*, *K. dujuanhuensis*, *K. dushanensis*, *K. extensum*, *K. fluminicola*, *K. guangdongensis*, *K. longirostrata*, *K. pini*, *K. puerensis*, *K. rostrata*, *K. sichuanensis*, *K. spatiosum*, *K. submersa*, *K. tectonae*, *K. thailandica* and *K. xishuangbannaensis* (Su et al. 2016; Jayawardena et al. 2022; Xu et al. 2023; Yang et al. 2023; Jin et al. 2024; Sruthi et al. 2024; this study).

Although *Kirschsteiniothelia* comprises numerous species, there are likely to be more undescribed species in this genus as predicted by Bhunjun et al. (2022). Most species have been reported as saprobes inhabiting terrestrial and freshwater environments in tropical and subtropical regions. However, *K. ebriosa* and *K. vinigena* have been identified from cork taint of sparkling wine (Bao et al. 2018; Rodríguez-Andrade et al. 2020; Sun et al. 2021; Jayawardena et al. 2022). Moreover, a report indicates the presence of an unidentified *Kirschsteiniothelia* species that is pathogenic to humans, causing infection superimposed on pre-existing non-infectious bursitis of the ankle. This identification was based on the examination of the strain's cultural colony and ITS gene fragment (Nishi et al. 2018). To date, there are 59 species of *Kirschsteiniothelia*, amongst which 18 have been reported only in their sexual morph, 32 reported in their asexual morph and six species documented in both morphs (Boonmee et al. 2012; Su et al. 2016; Sun et al. 2021; Xu et al. 2023; Zhang et al. 2023; de Farias et al. 2024; Sruthi et al. 2024; this study). Amongst the two asexual morphs that have been described so far, only the dendryphiopsis-like morph is linked to the sexual morph, while the sporidesmium-like state has not been associated with the sexual morph (Hawksworth 1985; Wang et al. 2004; Mulenko et al. 2008; Boonmee et al. 2012; Su et al. 2016; Sun et al. 2021; Xu et al.2023; de Farias et al. 2024).

In this study, we aimed to isolate microfungi from unidentified decaying wood collected in Hainan and Yunnan Provinces, China, as well as from *Edgeworthia chrysantha*, collected in Guizhou Province, China. This study has the following objectives: 1) to describe novel species associated with decaying wood through comprehensive morphological examinations and phylogenetic analyses of ITS, LSU and SSU rDNA sequence data; 2) to provide a checklist that includes host information, habitat preferences, availability of molecular data, morphological characteristics and country of origin.

Materials and methods

Sample collection, isolation and morphological studies

Decaying wood materials of *Edgeworthia chrysantha* and unidentified plants were collected from Zunyi City in Guizhou Province, Jianfengling National Forest Park, situated at the confluence of Ledong Li Autonomous County and Dongfang City in Hainan Province and Lushui City in Yunnan Province, China. These specimens were initially stored in Ziploc bags and observed using a stereomicroscope (Motic SMZ-171). The collection, observation and isolation were conducted following the methods outlined in Senanayake et al. (2020) and Tang et al. (2022). The observed features were measured using Tarosoft (R) Image Frame Work (version IFW 0.97) and photoplates were constructed using Adobe Photoshop 2019 (Adobe Systems, USA).

Specimens were deposited at the herbaria of the Kunming Institute of Botany, Chinese Academy of Sciences (HKAS), located in Kunming, China and the Guizhou Academy of Agriculture Sciences (GZAAS), situated in Guiyang, China. In addition, ex-type living cultures were preserved at the Kunming Institute of Botany Culture Collection (KUMCC) and the Guizhou Culture Collection (GZCC). Faces of Fungi and Fungal name numbers were obtained following the guidelines in Jayasiri et al. (2015), Wang et al. (2023) and Fungal names (2024). Species identification and establishment were determined following the guidelines outlined by Jeewon and Hyde (2016), Maharachchikumbura et al. (2021) and Pem et al. (2021).

DNA extraction, PCR amplification and sequencing

Freshly scraped mycelia from the pure cultures obtained by single spore isolation were transferred to 1.5 ml microcentrifuge tubes and stored in the refrigerator at -20 °C. Genomic DNA extraction was carried out using DNA extraction kits provided by Sangon Biotech (Shanghai) Co. Ltd., China. Polymerase Chain Reaction (PCR) was employed for DNA template amplification, using the following primer pairs: ITS5/ITS4 for ITS, NS1/NS4 for SSU (White et al. 1990) and LR0R/LR5 for LSU (Vilgalys and Hester 1990; Cubeta et al. 1991). Further details regarding DNA extraction, PCR amplification, sequencing and phylogenetic analyses are given in Tang et al. (2022, 2023).

In PCR amplification, the total volume of the PCR mixture was 50 µl, comprising the DNA template (2 µl), forward primer (2 µl), reverse primer (2 µl), 2 × Taq PCR Master Mix (25 µl) and 19 µl of double-distilled water. The PCR profiles consisted of 35 cycles, with annealing temperatures set at 52 °C for 1 minute and extension for 90 seconds at 72 °C for ITS, LSU and SSU loci. PCR products were verified on 1% agarose gel prior to submission to Sangon Biotech (Shanghai) Co., Ltd., China, for sequencing.

Phylogenetic analyses

Sequences obtained were subjected to a BLAST search in the NCBI database (https://blast.ncbi.nlm.nih.gov/Blast.cgi). Forward and reverse sequences were assembled using the Contig Express version 3.0.0 application. The ITS, LSU and SSU sequence data of *Kirschsteiniothelia* species were retrieved and downloaded from GenBank (Table 1). Individual sequences were aligned using

Table 1. Taxa used in this study and their respective GenBank accession numbers.

MAFFT version 7 (https://mafft.cbrc.jp/alignment/server/index.html) with the "auto" option (Katoh et al. 2017). The aligned sequences were trimmed using trimAl version 1.2 with the '-gt 0.6' command (Capella-Gutiérrez et al. 2009) and multiple genes were assembled using SequenceMatrix (Vaidya et al. 2011).

The phylogenetic analyses of the concatenated ITS, LSU and SSU sequences were conducted using Maximum Likelihood (ML) and Bayesian Inference (BI). Maximum Likelihood analysis was conducted using the IQ tree web server (http://iqtree.cibiv.univie.ac.at) and BI was carried out in the CIPRES web portal (Miller et al. 2010). The BI was performed using the tool "MrBayes on XSEDE" (Huelsenbeck and Ronquist 2001; Swofford 2002; Stamatakis et al. 2008; Ronquist et al. 2012). Prior to conducting BI, the model of evolution for each gene region was estimated using MrModelTest version 2 (Tang et al. 2023). The aligned Fasta file was converted into a Nexus format for subsequent Bayesian analysis using AliView version 1.27 (Daniel et al. 2010). Phylograms were

visualised using FigTree version 1.4.0 and edited in the Adobe Photoshop 2019 programme (Adobe Systems, USA) and Adobe Illustrator version 51.1052.0.0 (Adobe Inc., San Jose, California, USA).

Results

Phylogenetic analyses

According to the analysis of the concatenated ITS, LSU and SSU rDNA sequence data, all isolates collected in this study cluster within *Kirschsteiniothelia*. The dataset with 67 strains of *Kirschsteiniothelia*, including gaps, comprises 2290 characters (ITS: 1–506 base pairs (bp), LSU: 507–1330 bp and SSU: 1331–2283 bp). The highest-scoring RAxML tree is presented in Fig. 1, with a final ML optimisation likelihood value of -16683.670 (ln). The best-fit model for the BI analysis was GTR+I+G for ITS, LSU and SSU. Bayesian posterior probabilities (PP) from MCMC were analysed, achieving a final average standard deviation of split frequencies of 0.009914.

Taxonomy

***Kirschsteiniothelia atra* (Corda) D. Hawksw., Fungal Diversity 69: 37 (2014)**
Fungal Names number: FN 104401
Facesoffungi number: FoF01738
Fig. 2

≡ *Amphisphaeria aethiops* Sacc., Syll. fung. (Abellini) 1: 722 (1882)
= *Dendryphiopsis atra* (Corda) S. Hughes, Can. J. Bot. 31: 655 (1953)
≡ *Dendryphion atrum* Corda, Icon. fung. (Prague) 4: 33 (1840)
≡ *Kirschsteiniothelia aethiops* (Sacc.) D. Hawksw., J. Linn. Soc., Bot. 91(1–2): 185 (1985)

Description. ***Saprobic*** on decaying wood of *Edgeworthia chrysantha*. ***Sexual morph:*** see Hawksworth (1985). ***Asexual morph: Colonies*** on the natural substrate superficial, effuse, gregarious, dark brown to black, glistening. ***Mycelium*** immersed, composed of branched, septate, thin-walled, smooth, brown hyphae. ***Conidiophores*** 253–396 × 8–15.5 µm ($\bar{x}$ = 334.6 × 11.7 µm, n = 20), macronematous, mononematous, erect, straight or flexuous, cylindrical, septate, smooth, brown to dark brown, becoming paler towards the apex and comprising numerous short branches. ***Conidiogenous cells*** 14.5–29 × 5–10 µm ($\bar{x}$ = 20.6 × 6.8 µm, n = 30), tretic, integrated, sometimes percurrent, terminal, doliiform or lageniform, subhyaline to pale brown, with new cells developing from the apical or subapical part of the subtending cells. ***Conidia*** 32–56.5 × 11–19.5 µm ($\bar{x}$ = 42.3 × 14.5 µm, n = 30), solitary, acrogenous, cylindrical, sometimes clavate, 3–4-septate, constricted and darker at the septa, smooth, brown and rounded at the apex.

Culture characteristics. Conidia germinating on Potato Dextrose Agar (PDA) within 24 h, and producing germ tubes either from the apex or base. Colonies circular, flat, dense, radial sulcate, edge entire, pearl-gray on the surface, dark brown on the reverse and becoming grey-white along the margin.

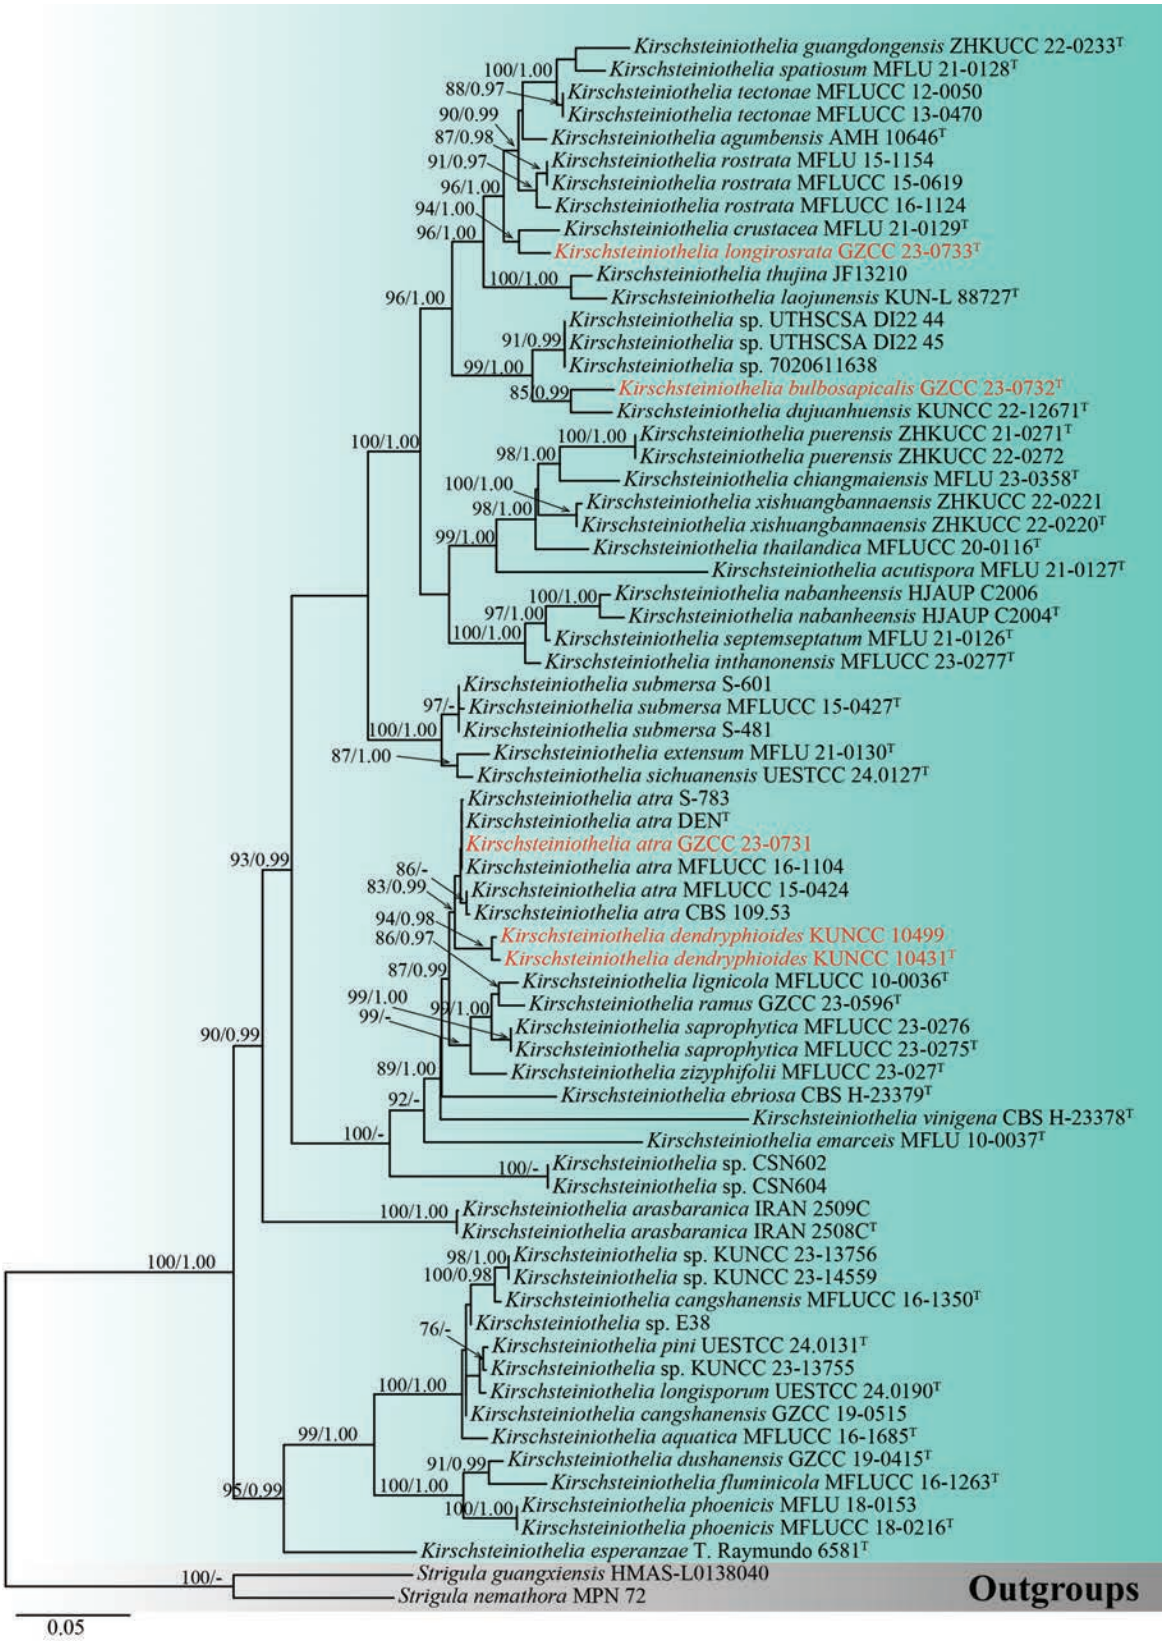

Figure 1. Phylogram of *Kirschsteiniothelia* taxa, based on the RAxML analysis of the combined ITS, LSU and SSU rDNA sequence dataset. Bootstrap support values for Maximum Likelihood (ML) equal to or greater than 75% and Bayesian posterior probabilities (PP) equal to or greater than 0.95 are shown above the nodes. The tree is rooted with *Strigula guangxiensis* (HMAS-L0138040) and *S. nemathora* (MPN 72). Newly-generated strains are denoted in red and type strains are indicated with a superscript "T".

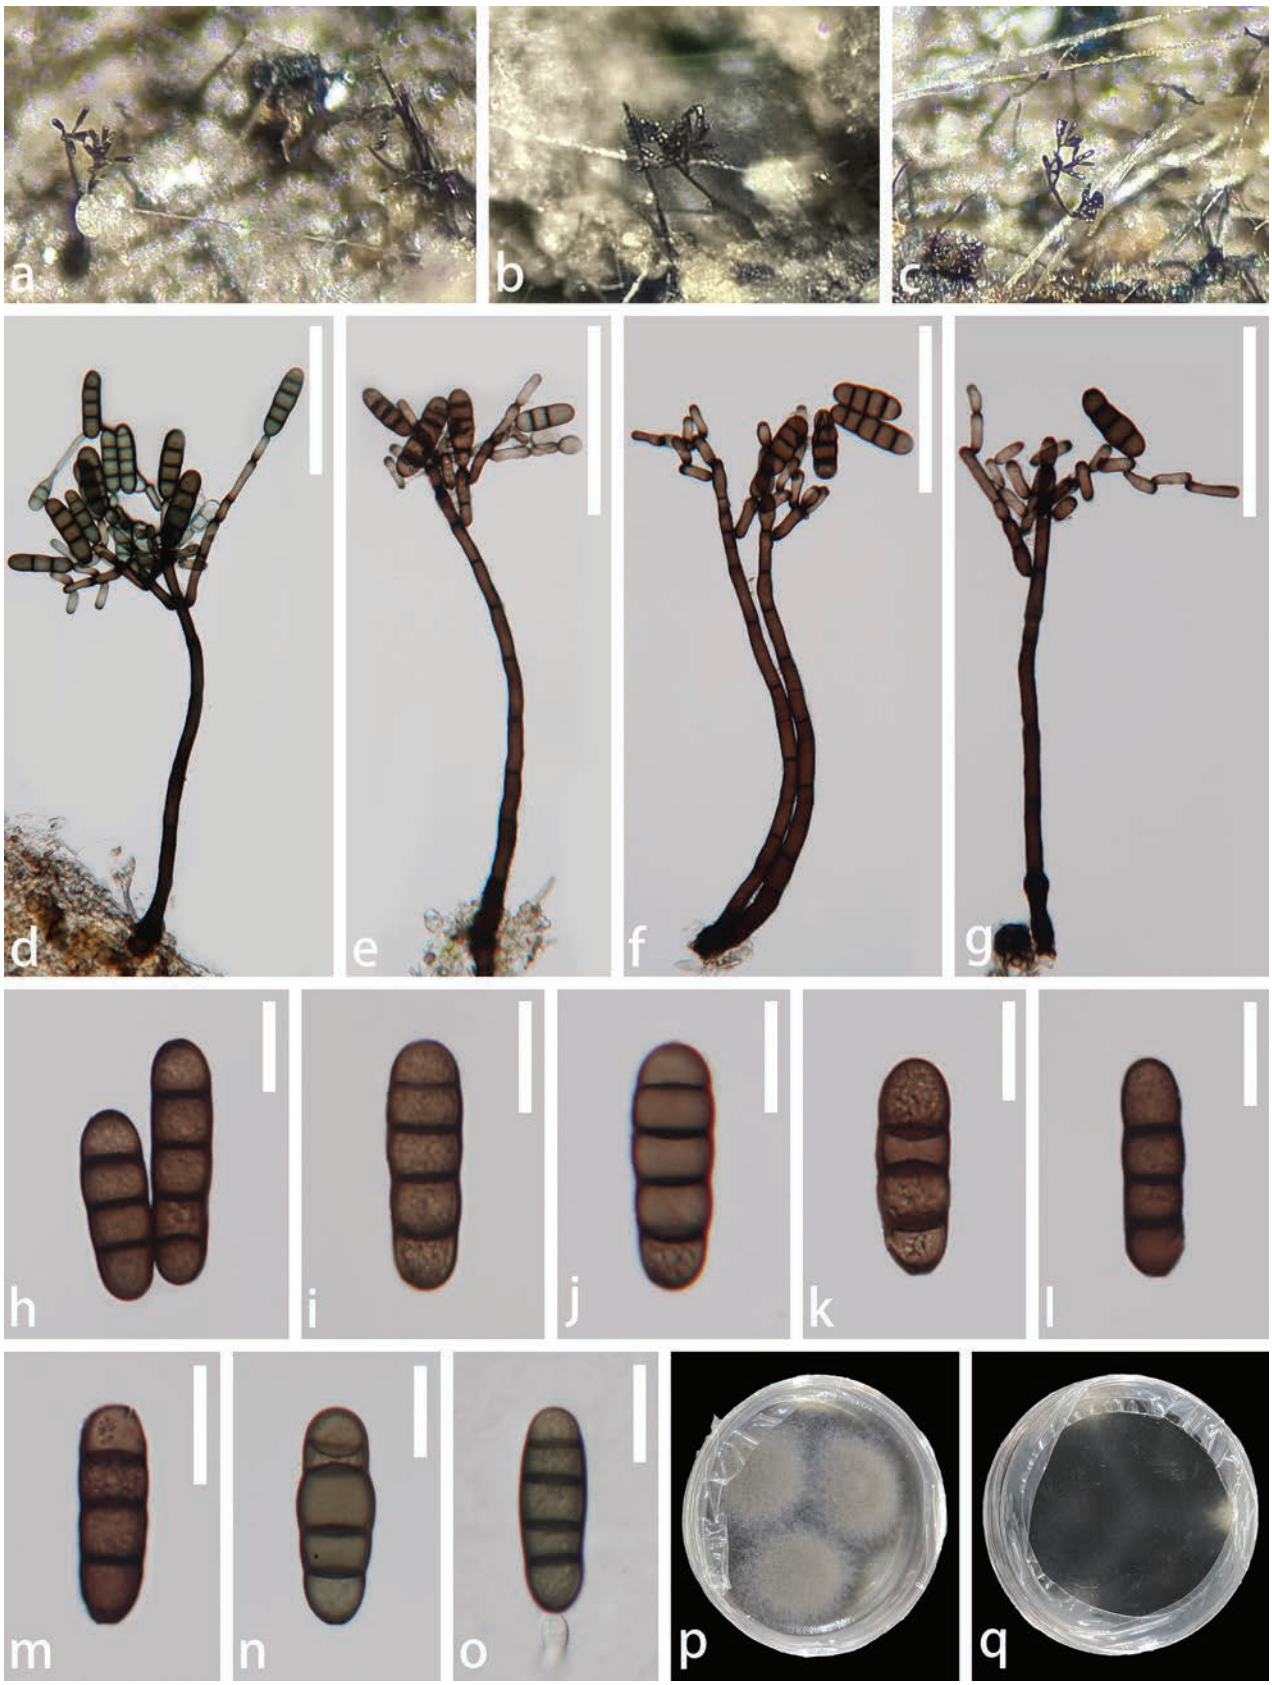

Figure 2. *Kirschsteiniothelia atra* (GZAAS 23-0807, new host record) **a–c** colonies on natural substrate **d–g** conidiophores and conidiogenous cells bearing conidia **h–n** conidia **o** a germinated conidium **p** upper surface view of culture **q** lower surface view of culture. Scale bars: 100 μm (**d–g**); 20 μm (**h–o**).

Material examined. China • Guizhou Province, Zunyi City, Suiyang County, saprobic on decaying branches of *Edgeworthia chrysantha*, 13 February 2023, Xue-Mei Chen, SY12 (GZAAS 23-0807), living culture GZCC 23-0731.

Known distribution (based on molecular data). China (Su et al. 2016; this study).

Known hosts (based on molecular data). *Edgeworthia chrysantha* (This study), Unidentified decaying wood (Su et al. 2016).

Note. Morphologically, our collection matches the characteristics of *Kirschsteiniothelia atra*, including macronematous, mononematous conidiophores with numerous short branches; tretic, doliiform, or lageniform conidiogenous cells that develop new cells from the apical or subapical part of the subtending cells; and cylindrical, occasionally clavate conidia that are 3–4-septate, constricted and darker at the septa, which are rounded at the apex (Su et al. 2016). In the phylogenetic analyses, our collection (GZCC 23-0731) clusters with *Kirschsteiniothelia atra* (CBS 109.53, DEN, MFLUCC 15-0424, MFLUCC 16-1104 and S–783) (Fig. 1). Excluding gaps, no difference was observed in the comparison of nucleotides across the ITS (491 bp), LSU (788 bp) and SSU (844 bp) regions between our collection and *Kirschsteiniothelia atra* (MFLUCC 16-1104). Based on these findings, we identify our isolate as *Kirschsteiniothelia atra*, following the guidelines established by Jeewon and Hyde (2016) and Maharachchikumbura et al. (2021). This is the first time *Kirschsteiniothelia atra* has been reported from *Edgeworthia chrysantha*.

***Kirschsteiniothelia bulbosapicalis* X. Tang, K.D. Hyde, Jayaward. & J.C. Kang, sp. nov.**

Fungal Names number: FN 572044

Facesoffungi number: FoF16485

Fig. 3

Etymology. The specific epithet '*bulbosapicalis*' refers to the bulbous area of the conidia at the apex.

Holotype. GZAAS 23-0808.

Description. ***Saprobic*** on unidentified decaying wood. ***Sexual morph:*** Undetermined. ***Asexual morph: Colonies*** on the natural substrate superficial, effuse, gregarious, hairy, black, glistening. ***Mycelium*** semi-immersed, on the substrate, pale brown to dark brown. ***Conidiophores*** (–47)58–128(–199) µm × 7.5–12.5(–16.5) µm ($\bar{x}$ = 86.7 × 10.6 µm, n = 15), macronematous, mononematous, solitary, straight or slightly flexuous, cylindrical, unbranched, septate, smooth, brown to dark brown, truncate at the apex and wider at the base. ***Conidiogenous cells*** 6–17 µm × 7–10.5 µm ($\bar{x}$ = 10.6 × 8.6 µm, n = 15), monoblastic, holoblastic, terminal, determinate, proliferating, cylindrical, brown to dark brown. ***Conidia*** 118–236.5 µm × 15–27 µm ($\bar{x}$ = 174.8 × 21 µm, n = 30), solitary, acrogenous, cylindrical, ovoid to obclavate, rostrate, smooth, straight or slightly curved, 8–13-septate, slightly constricted at the septa, olivaceous to reddish-brown to dark brown, bulbous at the apex and/or third or fourth cell, truncate at the base, with a spherical hyaline mucilaginous sheath.

Culture characteristics. Conidia germinating on PDA within 24 hours, producing germ tubes from the apex. Colonies displayed a circular morphology with an umbonate elevation, dense growth and a filiform margin. The surface

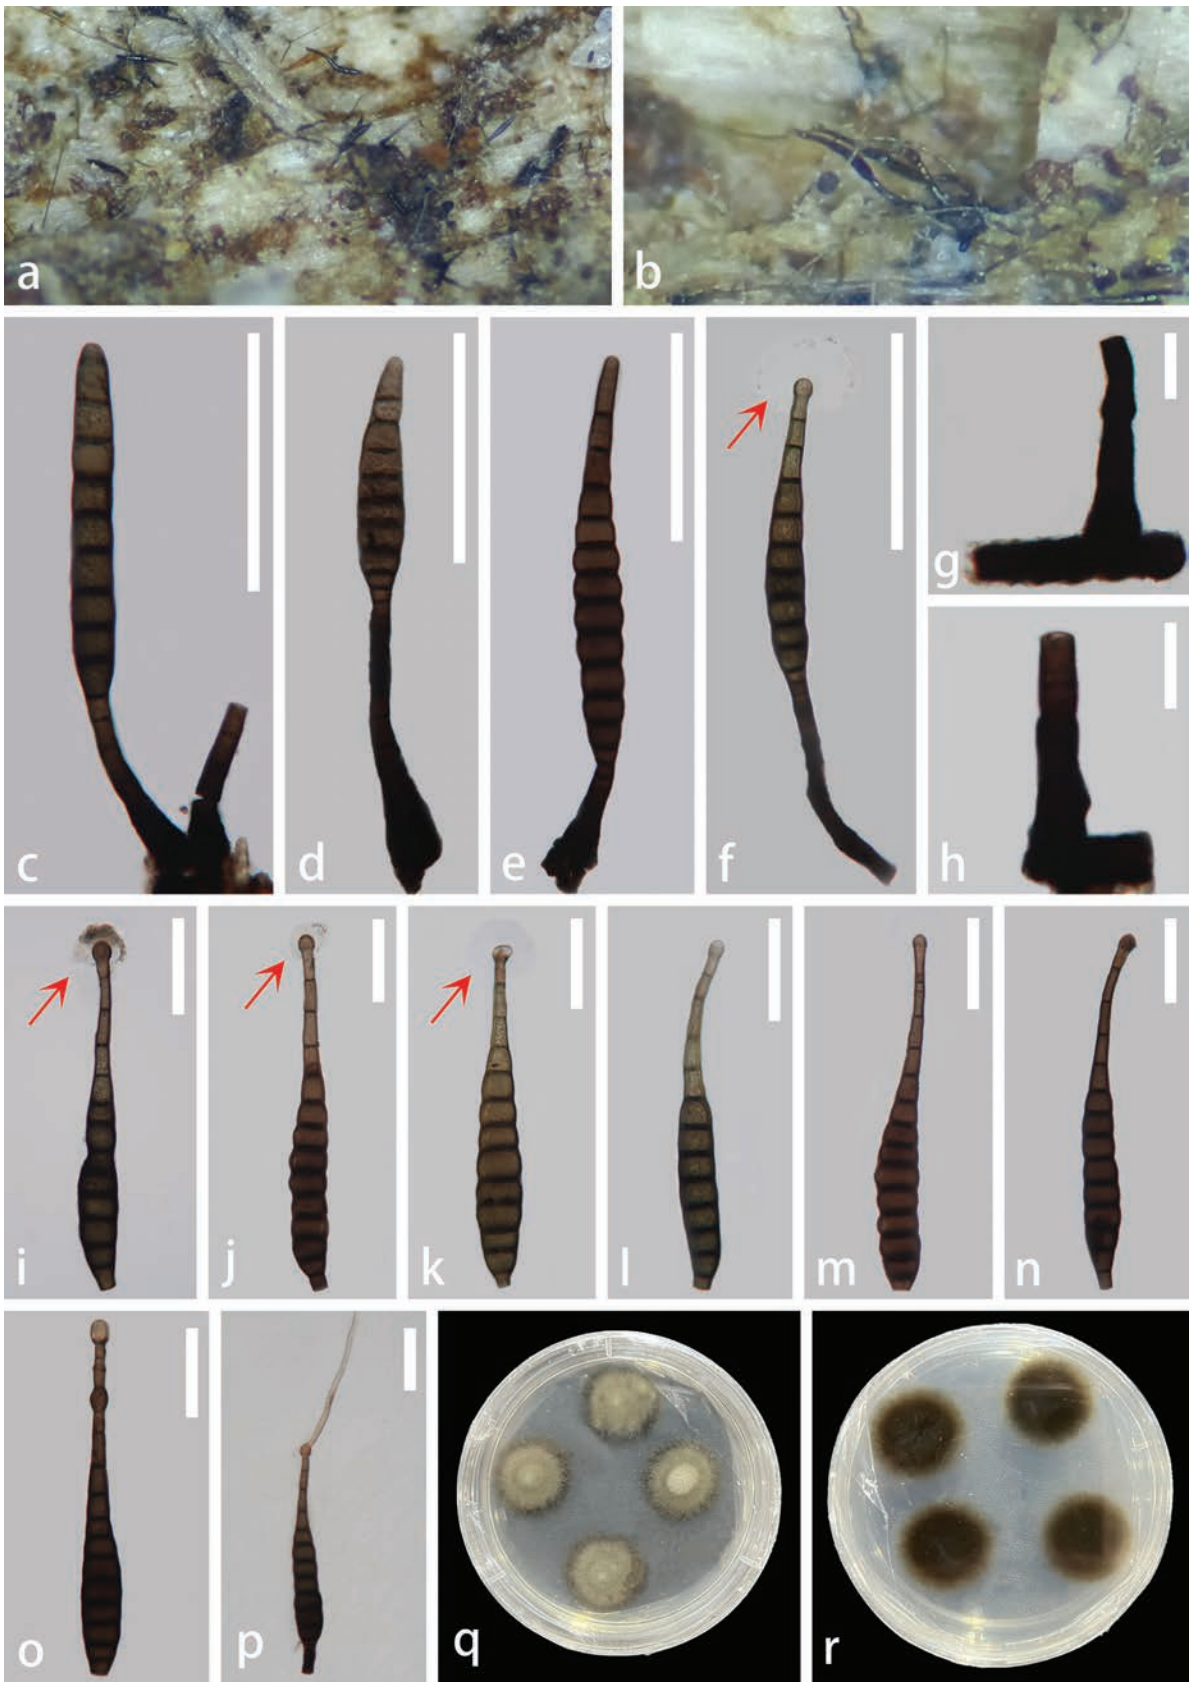

Figure 3. *Kirschsteiniothelia bulbosapicalis* (GZCC 23-0732, holotype) **a, b** colonies natural substrate **c–f** conidiophores, conidiogenous cells bearing conidia (red arrows indicate mucilaginous sheaths) **g, h** conidiophores **i–o** conidia (red arrows indicate mucilaginous sheaths) **p** a germinated conidium **q** upper surface view of culture **r** lower surface view of culture. Scale bars: 100 µm (**c–f**); 20 µm (**g, h**); 50 µm (**i–p**).

appeared greyish-green, occasionally exhibiting paler mycelium in the bulge region. The reverse colonies exhibited a circular shape with a filiform margin, displaying a dark brown colour, becoming olivaceous towards the periphery.

Material examined. China • Hainan Province, Jianfengling National Forest Park, saprobic on unidentified decaying wood, 23 August 2021, Zili Li, JBT04 (GZAAS 23-0808, holotype), ex-type living culture GZCC 23-0732.

Note. *Kirschsteiniothelia bulbosapicalis* exhibits sporidesmium-like characteristics and shares similar morphologies with other *Kirschsteiniothelia* species. However, *K. bulbosapicalis* can be distinguished from other *Kirschsteiniothelia* species in having different sizes of conidiophores, conidiogenous cells and the unique feature of its conidia, which comprises one or two bulbous structures at or near the apex, with a spherical hyaline mucilaginous sheath. Phylogenetically, *K. bulbosapicalis* is sister to *K. dujuanhuensis* (KUNCC 22-12671) with 85% ML and 0.99 PP support (Fig. 1). Similar to our new species, *K. dujuanhuensis* also comprises a spherical hyaline mucilaginous sheath. *Kirschsteiniothelia bulbosapicalis* is characterised by larger conidiophores [(–47)58.5–128(–199) µm × 7.5–12.5(–16.5) µm, L/W ratio = 8.2] compared to *K. dujuanhuensis* [29–74(–119) × 9–11 µm, L/W ratio = 5.1] and larger conidia (118–236.5 µm × 15–27 µm, L/W ratio = 8.3) compared to *K. dujuanhuensis* [(114–)122–155(–170) × 10–13(–16) µm, L/W ratio = 11.5]. In addition, *K. bulbosapicalis* exhibits cylindrical to ovoid or obclavate conidia with 8–13 septa and often consist of bulbous structures at the apex and/or the third or fourth cell, as well as a spherical hyaline mucilaginous sheath. In contrast, *K. dujuanhuensis* typically contains obclavate to subcylindrical conidia that are 6–15 septate.

In addition, the comparison of the nucleotides between the sequences of *K. bulbosapicalis* and *K. dujuanhuensis* showed differences of 9% (47/512 bp) across ITS, 1% (8/812 bp) across LSU and 0.1% (2/1003 bp) across SSU, excluding gaps. Based on these findings, we introduce *K. bulbosapicalis* as a novel species, in accordance with the guidelines established by Jeewon and Hyde (2016) and Maharachchikumbura et al. (2021).

Kirschsteiniothelia dendryphioides **X. Tang, K.D. Hyde, Jayaward. & J.C. Kang, sp. nov.**

Fungal Names number: FN 572046

Facesoffungi number: FoF16486

Figs 4, 5

Etymology. The specific epithet "*dendryphioides*" is derived from the resemblance to the dendryphiopsis-like features.

Holotype. HKAS 136930.

Description. ***Saprobic*** on an unidentified decaying wood. ***Sexual morph:*** Undetermined. ***Asexual morph: Colonies*** on the natural substrate superficial, effuse, scattered, hairy, black, glistening. ***Mycelium*** partly immersed, on the substrate, pale brown to dark brown. ***Conidiophores*** 179–467 × 4.5–8 µm ($\bar{x}$ = 318.2 × 6.1 µm, n = 10), macronematous, mononematous, erect, subscorpioid branched, straight or flexuous, cylindrical, septate, smooth, brown to dark brown, becoming paler towards the apex. ***Conidiogenous cells*** 9–19 × 4–8 µm ($\bar{x}$ = 13.3 × 6.1 µm, n = 30), monotretic, terminal or intercalary, integrated, some-

Figure 4. *Kirschsteiniothelia dendryphioides* (HKAS 136930, holotype) **a, b** colonies on natural substrate **c, d** conidiophores, conidiogenous cells bearing conidia **e–g** conidiogenous cells bearing conidia **h–o** conidia **p** upper surface view of culture **q** lower surface view of culture; Scale bars: 100 μm (**c, d**); 50 μm (**e**); 20 μm (**f–o**).

times percurrent, cylindrical, doliiform, mostly discrete, determinate, smooth, pale brown to brown, both ends appearing darker, with new cells developing from the apical or subapical part of the subtending cells. ***Conidia*** 30–55 × 9–13.5 μm ($\bar{x}$ = 40 × 11.1 μm, n = 30), solitary, acrogenous, cylindrical, oblong

Figure 5. *Kirschsteiniothelia dendryphioides* (HKAS 135651, paratype) **a, b** colonies on natural substrate **c, d** conidiophores, conidiogenous cells bearing conidia **e–g** conidiogenous cells bearing conidia **h–l** conidia **m** upper surface view of culture **n** lower surface view of culture. Scale bars: 100 μm (**c, d**); 20 μm (**e–l**).

and occasionally clavate, smooth, guttulate, 2–4-septate, slightly or deeply constricted and darker at the septa, brown, rounded at the apex and sometimes truncate at the base, exhibiting obtuse ends.

Culture characteristics. Conidia germinating on PDA within 24 hours. Colonies circular, characterised by dense, flat, spreading and fluffy growth, with an entire margin. The surface displayed a dark brown hue, while the reverse colonies exhibited a circular shape with an entire margin, also appearing dark brown.

Material examined. China • Yunnan Province, Lushui City, Sanhe Village, Gaoligong Mountain, saprobic on decaying wood in a freshwater stream, 5 May 2021, Rong-ju Xu, XS17 (HKAS 136930, holotype), ex-type living culture, KUNCC 10431; *ibid.* • saprobic on submerged decaying wood in freshwater habitats, 22 August 2021, Rong-ju Xu, SYC-05 (HKAS 135651, paratype), living culture, KUNCC 10499.

Notes. *Kirschsteiniothelia dendryphioides* exhibits dendryphiopsis-like characteristics and shares similar morphologies with other *Kirschsteiniothelia* species. However, *K. dendryphioides* differs from other species in the size of its conidiophores, conidiogenous cells and conidia. *Kirschsteiniothelia dendryphioides* is distinct from *K. atra* in having larger conidiophores (179–467 × 4.5–8 µm, L/W ratio = 52.2 vs. 148–228 µm × 6–8 µm, L/W ratio = 27), shorter conidiogenous cells (9–19 × 4–8 µm, L/W ratio = 2.2 vs. 25–33 µm × 5–7 µm, L/W ratio = 4.8) and smaller conidia (30–55 × 9–13.5 µm, L/W ratio = 3.6 vs. 54–63 ×14–18 µm, L/W ratio = 3.4).

The establishment of *Kirschsteiniothelia dendryphioides* as a new species is further supported by molecular data. Based on our phylogenetic analyses, *K. dendryphioides* strains (KUNCC 10431 and KUNCC 10499) form a subclade sister to the strains of *Kirschsteiniothelia atra* (CBS 109.53, DEN, MFLUCC 15-0424, MFLUCC 16-1104 and S-783) with 83% ML and 0.99 PP support (Fig. 1). The comparison of the nucleotides between the sequences of *K. dendryphioides* and *K. atra* (MFLUCC 16-1104) shows a difference of 1.9% (9/481 bp) across ITS and 2.4% (11/458 bp) across SSU, but no difference was observed across LSU (777 bp), excluding gaps. Based on these findings, we introduce *Kirschsteiniothelia dendryphioides* as a novel species, following guidelines outlined in Jeewon and Hyde (2016) and Maharachchikumbura et al. (2021). We were unable to compare the nucleotide differences across LSU and SSU of KUNCC 10499 as it lacks sequence data for these loci.

***Kirschsteiniothelia longirostrata* X. Tang, K.D. Hyde, Jayaward. & J.C. Kang, sp. nov.**

Fungal Names number: FN 572045
Facesoffungi number: FoF16487
Fig. 6

Etymology. The specific epithet '*longirostrata*' refers to the conidia containing a long rostrate.

Holotype. GZAAS 23-0809.

Description. ***Saprobic*** on an unidentified submerged decaying wood. ***Sexual morph:*** Undetermined. ***Asexual morph: Colonies*** on the natural substrate superficial, effuse, gregarious, hairy, black, glistening. ***Mycelium*** partly

Figure 6. *Kirschsteiniothelia longirostrata* (GZCC 23-0733, holotype) **a** unidentified submerged wood **b** colonies on natural substrate **c, d** conidiophores, conidiogenous cells **e–g** conidiophores, conidiogenous cells bearing conidia **h–p** conidia (red arrows indicate mucilaginous sheaths) **q** a germinated conidium; **r** Upper surface view of culture **s** lower surface view of culture. Scale bars: 100 μm (**c–g**); 20 μm (**h–q**).

immersed on the substrate, composed of branched, septate, smooth-walled hyphae, pale to dark brown. ***Conidiophores*** 80–252 × 4.5–9.5 µm ($\bar{x}$ = 161.3 × 6.8 µm, n = 20), macronematous, mononematous, solitary, cylindrical, straight, or slightly flexuous, unbranched, percurrent, smooth, guttulate, 4–13-septate, sometimes slightly constricted at the septa, brown to dark brown tapering towards the apex and wider at the base. ***Conidiogenous cells*** 6.5–16 × 5–9 µm ($\bar{x}$ = 13× 7 µm, n = 20), monoblastic, terminal or indeterminate, percurrently proliferating, cylindrical, pale brown to brown. ***Conidia*** 36.5–109(–160) × 8–16 µm ($\bar{x}$ = 71× 12 µm, n = 30), solitary, acrogenous, cylindrical, obpyriform to obclavate, rostrate 15–100(–120) × 2.5–6 µm ($\bar{x}$ = 48 × 4.3 µm, n = 30), smooth, straight or curved, guttulate, 6–18-septate, slightly constricted and darker at the septa, proliferating, pale brown to brown, becoming paler towards the apex, with a truncate base and a mucilaginous sheath surrounding the upper part of the apex.

Culture characteristics. Conidia germinating on PDA within 24 hours, producing germ tubes from the apex. Colonies displayed a circular morphology with dense, flat, spreading and fluffy growth, with an entire margin. The surface exhibited an olivaceous-green hue with a darker edge, while the reverse colonies displayed a circular shape with an entire margin, appearing blackish-green.

Material examined. China • Hainan Province, Jianfengling National Forest Park, saprobic on submerged unidentified decaying wood, 23 August 2021, Zili Li, T10 (GZAAS 23-0809, holotype) ex-type living culture GZCC 23-0733.

Notes. *Kirschsteiniothelia longirostrata* exhibits sporidesmium-like characteristics and shares similar features with other *Kirschsteiniothelia* species. *Kirschsteiniothelia longirostrata* can be distinguished from other *Kirschsteiniothelia* species in having different sizes and shapes of conidiophores, conidiogenous cells and unique features of conidia, such as obpyriform to obclavate, long rostrate, proliferating, with a mucilaginous sheath surrounding the upper part of the apex. Unlike *K. crustacea*, *K. longirostrata* has cylindrical, proliferating conidiogenous cells and obpyriform to obclavate conidia, with longer (15–100(–120) × 2.5–6 µm), guttulate, proliferating rostrate structures and a mucilaginous sheath surrounding the upper part of the apex.

Molecular data further supports the establishment of *Kirschsteiniothelia longirostrata* as a novel taxon. Based on our phylogenetic analyses, *K. longirostrata* is sister to *K. crustacea* (MFLU 21-0129) with 94% ML and 1.00 PP support (Fig.1). The comparison of the nucleotides between the sequences of *K. longirostrata* (GZCC 23-0733) and *K. crustacea* (MFLU 21-0129) shows differences of 8.4% (39/467 bp) across ITS and 0.7% (5/718 bp) across LSU, excluding gaps. However, we were unable to compare the nucleotide differences across SSU as *K. crustacea* lacks sequence data for this locus. Based on these findings, we introduce *Kirschsteiniothelia longirostrata* as a novel species, following guidelines outlined in Jeewon and Hyde (2016) and Maharachchikumbura et al. (2021).

Discussion

During surveys on saprobic fungi associated with woody plants in the subtropical and tropical forests of the Guizhou, Hainan and Yunnan Provinces in China, we discovered three previously undocumented taxa and one known species,

which belong to *Kirschsteiniothelia*. They were found on decaying wood, including some unidentified hosts and *Edgeworthia chrysantha*. All these species have been reported with their asexual morph, either exhibiting the dendryphiopsis-like or sporidesmium-like morphologies.

Our newly-described taxa include two sporidesmium-like species, namely *Kirschsteiniothelia bulbosapicalis* and *K. longirostrata* and one dendryphiopsis-like taxon, *K. dendryphioides*. Both *Kirschsteiniothelia bulbosapicalis* and *K. longirostrata* exhibit distinct characteristics from other species of *Kirschsteiniothelia*. *Kirschsteiniothelia bulbosapicalis* is characterised by acrogenous, cylindrical, ovoid, obclavate, rostrate, straight or slightly curved conidia with 8–13 septa, often bulbous at the apex and/or third or fourth cell, with a spherical hyaline mucilaginous sheath. *Kirschsteiniothelia longirostrata* displays solitary, acrogenous, cylindrical, obpyriform to obclavate, rostrate, smooth, straight or curved and guttulate conidia that are paler towards the apex, consisting of 6–18 septa, slightly constricted and darker at the septa, with a mucilaginous sheath surrounding the tail-like upper part of the apex. *Kirschsteiniothelia longirostrata* has the longest tail amongst all current *Kirschsteiniothelia* species, which proliferates from the apex of the conidium. Our phylogenetic analyses reveal that our new species belong to *Kirschsteiniothelia* with stable support values and, in particular, is closely related to *K. crustacea*.

Kirschsteiniothelia dendryphioides displays solitary, acrogenous, cylindrical, oblong and occasionally clavate, smooth, guttulate, 2–4-septate conidia with slightly or deeply constricted and darker at the septa, rounded at the apex and sometimes truncate at the base, exhibiting obtuse ends. However, *Kirschsteiniothelia dendryphioides* is characterised by larger conidiophores, shorter conidiogenous cells and smaller conidia when compared to *K. atra*. Although they are morphologically similar, there are also sufficient dissimilarities in the DNA sequence data.

The new host record for *Kirschsteiniothelia atra* shows characteristics of solitary, acrogenous, cylindrical, sometimes clavate conidia that are 3–4-septate, constricted and darker at the septa and smooth and rounded at the apex. Based on a comparison of morphological and phylogenetic analyses, no significant differences were observed in the DNA base pairs and the morphological variations fall within the range of intraspecific diversity. Therefore, we identified our new collection (GZCC 23–0731) as the known species *K. atra*. Furthermore, this report extends the known host range of *K. atra* (Table 2).

Whether we can use sporidesmium-like and dendryphiopsis-like morphs to differentiate species is currently obscure. Based on our phylogeny, species with sporidesmium-like and dendryphiopsis-like morphs do constitute distinct clades. There are three dendryphiopsis-like species (*K. inthanonensis*, *K. nabanheensis* and *K. septemseptatum*) that constitute a strongly-supported subclade, but they are nested within sporidesmium-like species. Therefore, segregating species based on this aspect should be dealt with caution. As with other asexual fungi, some species of *Kirschsteiniothelia* occur solely in the sexual morph and, hence, we are unable to compare their morphologies with other asexual species.

Besides establishing three novel *Kirschsteiniothelia* species and a new host record, we provide a checklist of all *Kirschsteiniothelia* taxa (Table 2), which incorporate 41 asexual morph species, amongst which 21 exhibit the sporidesmi-

um-like morph, while 20 display the dendryphiopsis-like features (Hawksworth 1985; Boonmee et al. 2012; Su et al. 2016; Sun et al. 2021; Xu et al. 2023; de Farias et al. 2024; Jin et al. 2024; Tian et al. 2024). This checklist includes data on the host, habitat preferences, reported morphology, country of origin and availability of molecular data for all species of *Kirschsteiniothelia*. The checklist also provides the latest ecological information of species in the genus.

From the checklist (Table 2), we decipher that most *Kirschsteiniothelia* species have been reported from China (23 species), followed by Thailand (14 species), with a few distributed across different countries including Australia, Belgium, Canada, Czechia, France, Germany, Greece, Italy, India, Iran, Mexico, New Zealand, Poland, Russian Federation, Sweden, Switzerland, South Africa, Spain, United Kingdom and USA (Boonmee et al. 2012; Mehrabi et al. 2017; Bao et al. 2018; Rodríguez-Andrade et al. 2020; Jayawardena et al. 2022; Senanayake et al. 2023; Liu et al. 2023b; Yang et al. 2023; de Farias et al. 2024; Louangphan et al. 2024). As noted in Table 2, the proportion of new species of *Kirschsteiniothelia* discovery in China and Thailand reaches 63%, while other countries and regions have only sporadically discovered one or two species. Hence, we presume that *Kirschsteiniothelia* is highly diverse with many potentially more unknown species and other tropical and subtropical regions that should be explored. In addition, most new species in China and Thailand were primarily found in tropical and subtropical regions, with nearly all species growing on decayed wood (Bao et al. 2018; Rodríguez-Andrade et al. 2020; Sun et al. 2021; Jayawardena et al. 2022; Senanayake et al. 2023; Liu et al. 2023b; Yang et al. 2023; de Farias et al. 2024; Louangphan et al. 2024). We speculate that the high proportion of new species discovered in China and Thailand can be attributed to the following reasons: 1) The tropical/subtropical climatic conditions in China and Thailand are suitable for the growth of these species, with optimal temperature and humidity levels that favour spore germination and colony growth; 2) Samples of *Kirschsteiniothelia* are easily observed on natural substrates and easy to collect; 3) They proliferate quite easily and are potentially good decomposers of substrates and they grow well on most common culture media without requiring specific cultivation conditions; 4) There are many mycologists in China and Thailand who are actively involved in fungal taxonomy and are more likely to discover more new species.

Most species of *Kirschsteiniothelia* are saprobes occurring mainly in terrestrial and followed by freshwater habitats, with only a few taxa reported from environments, such as cork stoppers and as a pathogen that infects human beings (Hawksworth 1985; Boonmee et al. 2012; Su et al. 2016; Nishi et al. 2018; Rodríguez-Andrade et al. 2020; Sun et al. 2021; Xu et al. 2023; de Farias et al. 2024). According to our results, species of *Kirschsteiniothelia* are also present in various habitats, albeit in small numbers. That may be because most studies have overlooked these more specific habitats. We recommend that future research should focus on exploring this genus in diverse environments to potentially discover additional species. In addition, most of the newly-discovered species are asexual on decayed wood samples. The latter provides ample organic nutrients which favour the emergence of the asexual morph and allows them to colonise new areas and propagate (Zalamea et al. 2016; Liu et al. 2023a).

Table 2. *Kirschsteiniothelia* species and data related to their host, habitat, country and reported morph.

Taxa	Host	Habitat	Morphological character	Asexual Morph character	Country	Molecular data	References

N/A: data not available; **A**: data available.

From a morphological perspective, the sporidesmium-like species are more diverse compared to the dendryphiopsis-like taxa. Interspecies differences are mainly attributed to the number and size of the conidiophores, conidiogenous cells and septa in the conidia. However, relying only on these features for species delineation is challenging and insufficient. Prior to the incorporation of molecular data, the taxonomy of *Kirschsteiniothelia* was challenging, resulting in controversial classifications. This genus was initially accommodated in Pleosporaceae by Hawksworth (1985) and Barr (1987), but later transferred to Pleomassariaceae by Barr (1993), based on morphological data. Based on molecular data, Schoch et al. (2006) suggested that *Kirschsteiniothelia* does not belong to any family within Pleosporales, but would rather be in a new family. Subsequently, Boonmee et al. (2012) introduced Kirschsteiniotheliaceae to accommodate *Kirschsteiniothelia* species, based on morphology and phylogenetic analyses. Hernández-Restrepo et al. (2017) established a novel order, Kirschsteiniotheliales, to accommodate the Kirschsteiniotheliaceae taxa. Subsequent studies have followed this classification, using ITS, LSU and SSU rDNA sequence data in their phylogenies (Sun et al. 2021; Xu et al. 2023; de Farias et al. 2024).

At present, most studies use LSU, ITS and SSU rDNA genes for inferring phylogeny relationships amongst *Kirschsteiniothelia* species. Despite close morphological similarities and overlap amongst species, we noted that there are rather unexpected sequence dissimilarities across the different genes analysed here. We presume that, despite high morphological similarities, these asexual species are characterised by high genetic diversity. This difference in genetic trait presumably enables them to adapt and flourish in different environments, gives them better chances of survival and drives speciation. So far, the ITS, LSU and SSU rDNA genes have most commonly been used to identify species within this genus, but as the number of species increases, we recommend incorporating protein genes like *tub*, *tef1-α* and *rpb2* (Badotti et al. 2017).

Acknowledgements

The author would like to express gratitude to Shaun Pennycook for his valuable suggestions on naming the new fungus. Xia Tang also wishes to thank Mae Fah Luang University for the Thesis Writing Grant and for awarding me a tuition scholarship for my Ph.D. studies at Mae Fah Luang University, Thailand. Rajesh Jeewon thanks the University of Mauritius in Reduit, Mauritius.

Abstract

Fungi are one of the most diverse groups of organisms on Earth, in which the wood-inhabiting fungi play an important role in forest ecosystem processes and functions. Four new wood-inhabiting fungi, *Lyomyces hengduanensis*, *L. niveomarginatus*, *L. wumengshanensis* and *L. zhaotongensis*, are proposed, based on morphological features and molecular evidence. *Lyomyces hengduanensis* differs in the brittle basidiomata with pruinose hymenial surface, a monomitic hyphal system and ellipsoid basidiospores (3.5–6 × 3–4.5 µm). *Lyomyces niveomarginatus* is distinguished by the subceraceous basidiomata with crackled hymenial surface, a monomitic hyphal system and ellipsoid basidiospores (4.5–7 × 3–4 µm). *Lyomyces wumengshanensis* is distinguished by the grandinioid hymenial surface, a monomitic hyphal system and ellipsoid to broad ellipsoid basidiospores (4–6 × 3–5 µm). *Lyomyces zhaotongensis* is unique in the grandinioid hymenial surface, a monomitic hyphal system and broadly ellipsoid basidiospores measuring as 2.6–3.5 × 2.5–3 µm. Sequences of ITS and nLSU rRNA markers of the studied samples were generated and phylogenetic analyses were performed using the Maximum Likelihood, Maximum Parsimony and Bayesian Inference methods. The phylogram, based on the ITS+nLSU rDNA gene regions, included three genera within the Schizoporaceae viz. *Fasciodontia*, *Lyomyces* and *Xylodon*, in which the four new species were grouped into *Lyomyces*. The phylogenetic tree inferred from the ITS sequences highlighted that *L. hengduanensis* group with *L. zhaotongensis* and then closely grouped with *L. crustosus*, *L. ochraceoalbus*, and *L. vietnamensis*. The new taxon *L. niveomarginatus* was retrieved as a sister to *L. juniperi*. The new species *L. wumengshanensis* was sister to *L. macrosporus*. The new taxon *L. zhaotongensis* grouped with *L. hengduanensis* and then closely grouped with *L. crustosus*, *L. ochraceoalbus* and *L. vietnamensis*.

Introduction

Fungi are one of the most diverse groups of organisms on Earth and play an indispensable role in the forest ecosystem processes and functioning (Hyde 2022; Guan et al. 2023; Deng et al. 2024a). The wood-inhabiting fungal family

Schizoporaceae Jülich includes many variations of the fruiting body types within the order Hymenochaetales Oberw. (Larsson et al. 2006; Wu et al. 2022a; Guan et al. 2023; Zhang et al. 2024) and it comprises a number of representative wood-inhabiting fungal taxa, including diverse hymenophoral morphologies as hydnoid, corticioid and polyporoid (Yurchenko and Wu 2016; Riebesehl and Langer 2017; Yurchenko et al. 2017; Cui et al. 2019; Riebesehl et al. 2019; Jiang et al. 2021; Wu et al. 2022a, 2022b; Guan et al. 2023; Deng et al. 2024a, b; Zhang et al. 2024). In addition, taxa of the family Schizoporaceae are widely found in different continents, causing white rot (Langer 1994; Luo et al. 2022; Guan et al. 2023; Zhang et al. 2024).

The genus *Lyomyces* P. Karst. is typified by *L. sambuci* (Pers.) P. Karst. It is characterised by the resupinate-to-effused basidiomata with a smooth-to-odontioid hymenophore, a monomitic hyphal system with generative hyphae bearing clamp connections, the presence of several types of cystidia and with smooth, thin- to slightly thick-walled basidiospores (Karsten 1881; Bernicchia and Gorjón 2010). Based on the MycoBank database (http://www.mycobank.org, accessed on 25 April 2024) and the Index Fungorum (http://www.indexfungorum.org, accessed on 25 April 2024), *Lyomyces* has 55 specific and infraspecific names registered, of which approximately 41 species of *Lyomyces* are currently known (Rabenhorst 1851; Karsten 1881; Karsten 1882; Cunningham 1959; Cunningham 1963; Wu 1990; Hjortstam and Ryvarden 2009; Xiong et al. 2009; Dai 2010; Dai 2011; Yurchenko and Wu 2013; Gafforov et al. 2017; Riebesehl and Langer 2017; Yurchenko et al. 2017; Chen and Zhao 2020; Yurchenko et al. 2020; Luo et al. 2021b; Luo et al. 2021c; Viner et al. 2022; Guan et al. 2023).

On the basis of the frequent inclusion of data from DNA sequences in many phylogenetic studies, the classification of the wood-inhabiting fungi has been updated continuously (Yurchenko et al. 2020). These pioneering research studies into the family Schizoporaceae were just the prelude to the molecular systematics period (Guan et al. 2023; Zhang et al. 2024). The genus *Hyphodontia* s.l. was indicated to be a polyphyletic group, in which the genera *Xylodon* (Pers.) Gray and *Kneiffiella* P. Karst. included the largest number of species (Yurchenko and Wu 2016; Riebesehl and Langer 2017; Riebesehl et al. 2019). Due to the lack of sequences of some wood-inhabiting fungal taxa, it is difficult to clearly distinguish many genera in this family Schizoporaceae using molecular data; therefore, a broad concept of *Hyphodontia* s.l. was accepted (Yurchenko and Wu 2016; Riebesehl and Langer 2017; Wang and Chen 2017; Riebesehl et al. 2019). Based on the nuclear DNA sequence data, six well-distinguished clades as *Hastodontia* clade, *Hyphodontia* clade, *Lagarobasidium* clade, *Kneiffiella-Alutaceodontia* clade, *Xylodon-Lyomyces-Rogersella* clade and *Xylodon-Schizopora-Palifer* clade, were included, based on the phylogenetical studies for *Hyphodontia* s.l., in which the genus *Lyomyces* was nested within the *Xylodon-Lyomyces-Rogersella* clade (Yurchenko and Wu 2013). The research revealed that *Hyphodontia* s.l. was divided into six genera, viz., *Hastodontia* (Parmasto) Hjortstam & Ryvarden, *Hyphodontia* J. Erikss., *Kneiffiella*, *Lagarobasidium* Jülich, *Lyomyces* and *Xylodon*, in which 35 new combinations were proposed, including fourteen *Lyomyces* species (Riebesehl and Langer 2017). On the basis of the sequences of the internal transcribed spacer (ITS) and the nuclear large subunit (nLSU) ribosomal DNA gene, the phylogenetic analysis clarified that the *Lyomyces sambuci* complex divided into four new

species (Yurchenko et al. 2017). Riebesehl et al. (2019) clarified the generic concept and their phylogenetic reconstruction of *Lyomyces* and the species *L. sambuci* was sister to *L. crustosus* (Pers.) P. Karst (Riebesehl et al. 2019). Based on a combination of the morphological and molecular evidence, the fungal diversity of the family Schizoporaceae was analysed, in which six new species were described: *L. fissuratus* C.L. Zhao, *L. fumosus* C.L. Zhao, *L. niveus* C.L. Zhao, *L. ochraceoalbus* C.L. Zhao, *L. albopulverulentus* C.L. Zhao and *L. yunnanensis* (Luo et al. 2021b, 2021c; Guan et al. 2023).

During the investigations of the wood-inhabiting fungi, we collected four new Hymenochaetales taxa from Yunnan Province, China, that could not be assigned to any described species of the order. We present the morphological characteristics and phylogenetic analyses with ITS and nLSU that support the four species in the genus *Lyomyces*.

Materials and methods

Morphology

Fresh basidiomata of the fungi growing on the angiosperm branch were collected from the Honghe, Lincang, Puer, Wenshan and Zhaotong of Yunnan Province, P.R. China after recording important information (Rathnayaka et al. 2024). Specimens were dried in an electric food dehydrator at 40 °C (Hu et al. 2022), then sealed and stored in an envelope bag and deposited in the Herbarium of the Southwest Forestry University (SWFC), Kunming, Yunnan Province, P.R. China. Macromorphological descriptions were based on field notes and photos were captured in the field and lab. Colour terminology follows Petersen (Petersen 1996). Micromorphological data were obtained from the dried specimens when observed under a light microscope following the previous study (Guan et al. 2023). The following abbreviations are used: KOH = 5% potassium hydroxide water solution, CB = Cotton Blue, CB– = acyanophilous, IKI = Melzer's Reagent, IKI– = both inamyloid and indextrinoid, L = mean spore length (arithmetic average for all spores), W = mean spore width (arithmetic average for all spores), Q = variation in the L/W ratios between the specimens studied and n = a/b (number of spores (a) measured from given number (b) of specimens).

Molecular phylogeny

The EZNA HP Fungal DNA Kit (Omega Biotechnologies Co., Ltd., Kunming, China) was used to extract DNA with some modifications from the dried specimens. The nuclear ribosomal ITS region was amplified with primers ITS5 and ITS4 (White et al. 1990). The PCR procedure for ITS was as follows: initial denaturation at 95 °C for 3 min, followed by 35 cycles at 94 °C for 40 s, 58 °C for 45 s and 72 °C for 1 min and a final extension of 72 °C for 10 min. The nuclear nLSU region was amplified with primer pair LR0R and LR7 (Rehner and Samuels 1994). The PCR procedure for nLSU was as follows: initial denaturation at 94 °C for 1 min, followed by 35 cycles at 94 °C for 30 s, 48 °C for 1 min and 72 °C for 1.5 min and a final extension of 72 °C for 10 min. The PCR procedure for ITS and nLSU followed the previous study (Zhao and Wu 2017). All newly-generated sequences were deposited in NCBI GenBank (https://www.ncbi.nlm.nih.gov/genbank/) (Table 1).

The sequences were aligned in MAFFT version 7 (Katoh et al. 2019) using the G-INS-i strategy. The alignment was adjusted manually using AliView version 1.27 (Larsson 2014). The sequence alignments were deposited in figshare (DOI: 10.6084/m9.figshare.27166521). Sequences of *Hymenochaete ochromarginata* P.H.B. Talbot and *Hymenochaete rubiginosa* (Dicks.) Lév., retrieved from GenBank, were used as the outgroups in the ITS+nLSU analysis (Fig. 1). The sequence alignments were deposited in figshare (DOI: 10.6084/m9.figshare.27166521). Sequences of *Xylodon quercinus* (Pers.) Gray and *Xylodon ramicida* Spirin & Miettinen, retrieved from GenBank, were used as the outgroups in the ITS analysis (Fig. 2) (Guan et al. 2023; Zhang et al. 2024).

Maximum Parsimony (MP), Maximum Likelihood (ML) and Bayesian Inference (BI) analyses were applied to the combined three datasets following a previous study (Zhao and Wu 2017). All characters were equally weighted and gaps were treated as missing data. Trees were inferred using the heuristic search option with TBR branch swapping and 1,000 random sequence additions. Max-trees were set to 5,000, branches of zero length were collapsed and all parsimonious trees were saved. Clade robustness was assessed using bootstrap

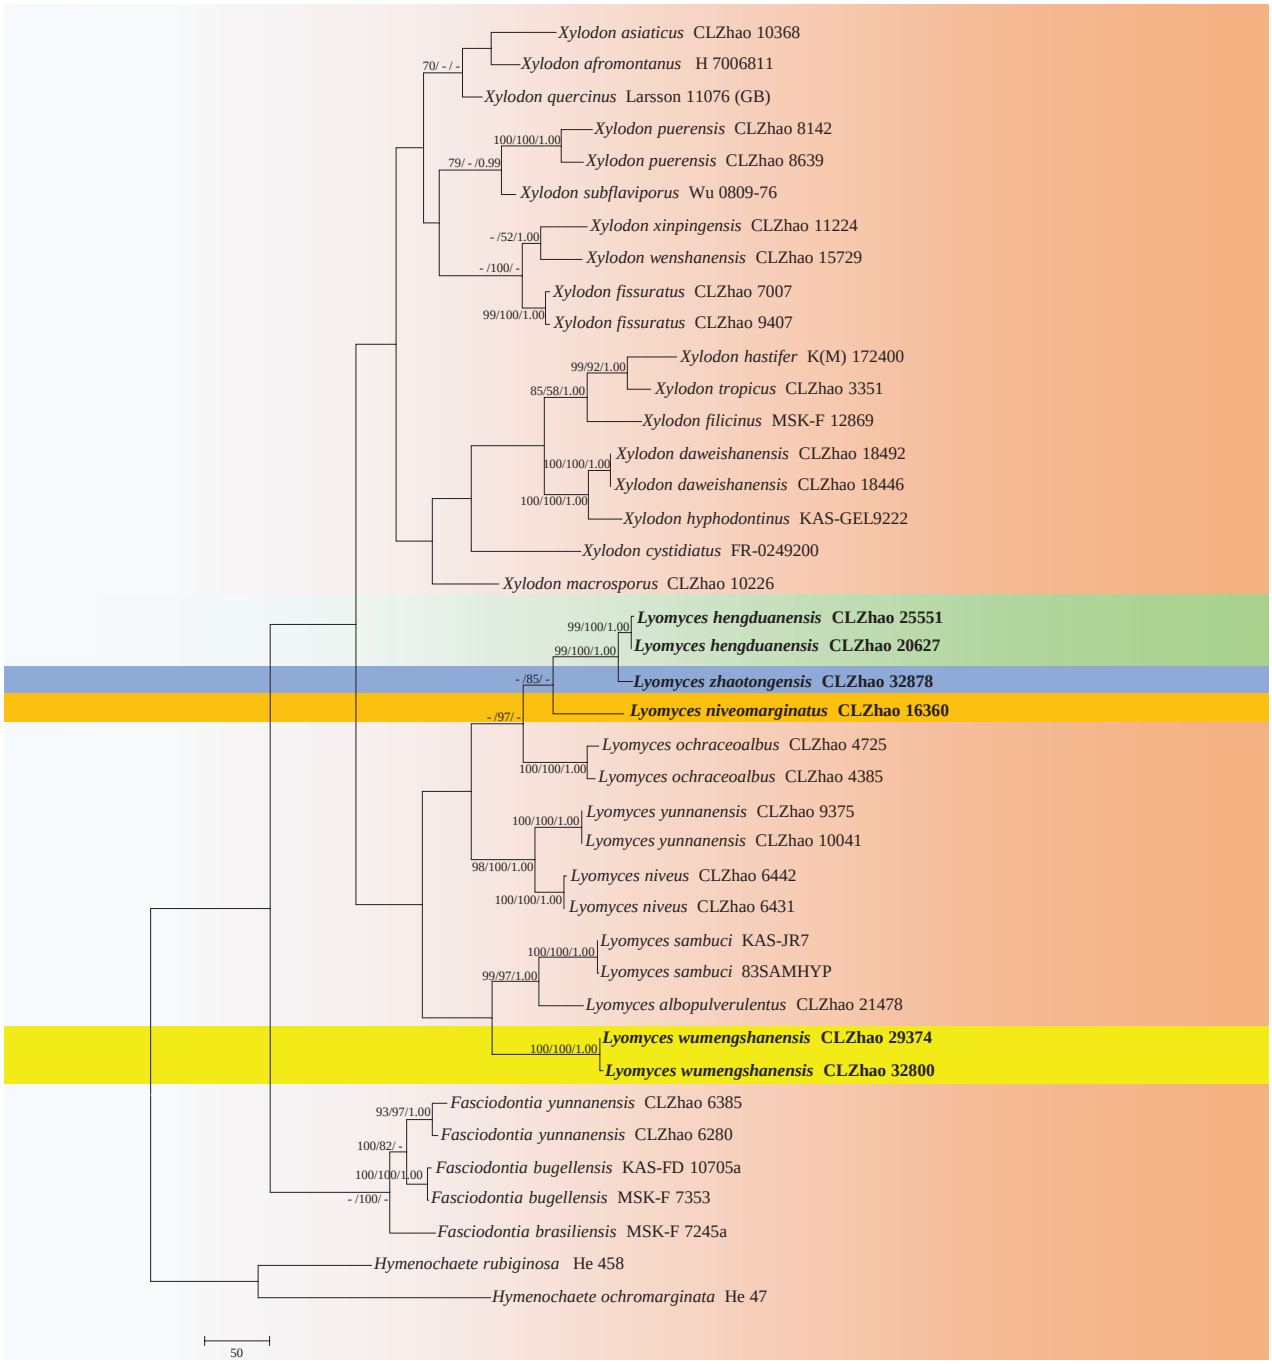

Figure 1. Maximum Parsimony strict consensus tree illustrating the phylogeny of four new species and related species in *Lyomyces* within Schizoporaceae, based on ITS+nLSU sequences. Branches are labelled with Maximum Likelihood bootstrap values ≥ 70%, parsimony bootstrap values ≥ 50% and Bayesian posterior probabilities ≥ 0.95, respectively.

(BT) analysis with 1,000 pseudo-replicates (Felsenstein 1985). Descriptive tree statistics - tree length (TL), composite consistency index (CI), composite retention index (RI), composite rescaled consistency index (RC) and composite homoplasy index (HI) - were calculated for each maximum parsimonious tree generated. The combined dataset was also analysed using Maximum Likelihood (ML) in RAxML-HPC2 through the CIPRES Science Gateway (Miller et al. 2012). Branch support (BS) for the ML analysis was determined by 1000 bootstrap pseudo-replicates.

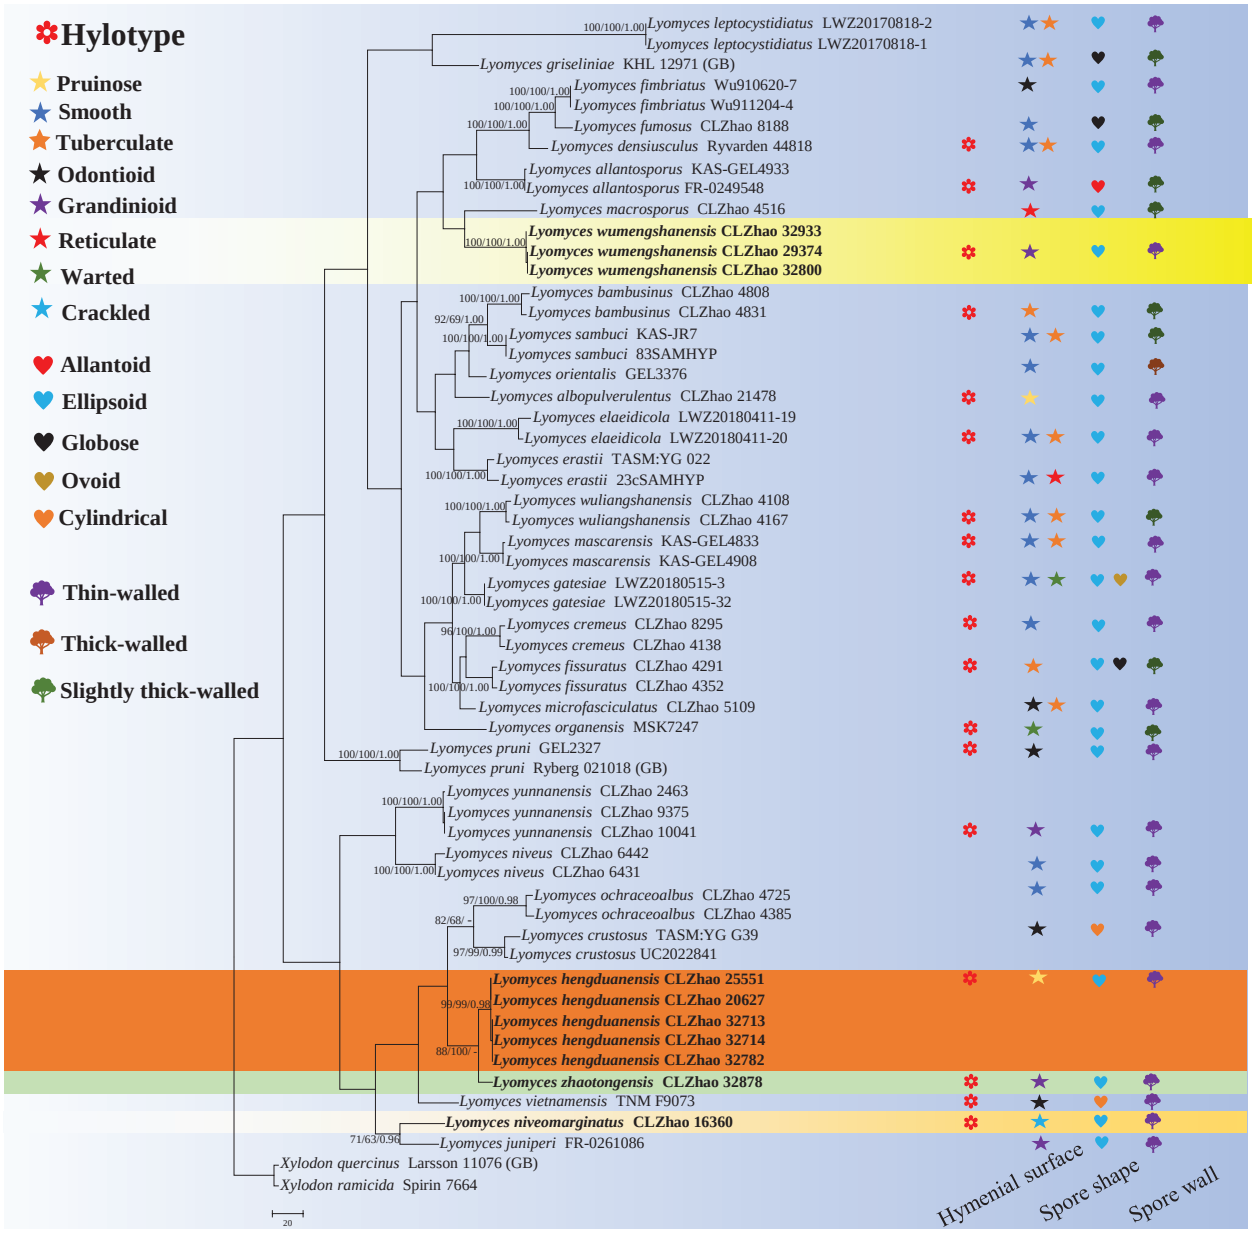

Figure 2. Maximum parsimony strict consensus tree illustrating the phylogeny of the four new species and related species in *Lyomyces*, based on ITS sequences. Branches are labelled with Maximum Likelihood bootstrap values > 70%, parsimony bootstrap values > 50% and Bayesian posterior probabilities > 0.95, respectively.

MrModelTest 2.3 (Nylander 2004) was used to determine the best-fit evolution model for each dataset for Bayesian Inference (BI), which was performed using MrBayes 3.2.7a with a GTR+I+G model of DNA substitution and a gamma distribution rate variation across sites (Ronquist et al. 2012). A total of four Markov chains were run for two runs from random starting trees for 1.905 million generations for ITS+nLSU (Fig. 1) and 2 million generations for ITS (Fig. 2), with trees and parameters sampled every 1,000 generations. The first quarter of all of the generations were discarded as burn-in. A majority rule consensus tree was computed from the remaining trees. Branches were considered as significantly supported if they received a Maximum Likelihood bootstrap support value (BS) of ≥ 70%, a Maximum Parsimony bootstrap support value (BT) of ≥ 70% or a Bayesian Posterior Probability (BPP) of ≥ 0.95.

Results

Molecular phylogeny

The ITS+nLSU dataset (Fig. 1) comprised sequences from 40 fungal specimens representing 29 taxa. The dataset had an aligned length of 2,112 characters, of which 1,298 characters were constant, 254 were variable and parsimony-uninformative and 560 were parsimony-informative. Maximum parsimony analysis yielded one equally parsimonious tree (TL = 2,513, CI = 0.4990, HI = 0.5010, RI = 0.6658 and RC = 0.3322). The best model of nucleotide evolution for the ITS+nLSU dataset estimated and applied in the Bayesian analysis was found to be GTR+I+G. Bayesian analysis and ML analysis resulted in a similar topology as in the MP analysis. The Bayesian analysis had an average standard deviation of split frequencies = 0.009992 (BI) and the effective sample size (ESS) across the two runs is double the average ESS (avg. ESS) = 2078.5. The phylogram, based on the ITS+nLSU rDNA gene regions (Fig. 1), included three genera within Schizoporaceae (Hymenochaetales), which were *Fasciodontia*, *Lyomyces* and *Xylodon*, in which four new species were grouped into the genera *Lyomyces*.

The ITS dataset (Fig. 2) comprised sequences from 57 fungal specimens representing 33 taxa. The dataset had an aligned length of 696 characters, of which 270 characters were constant, 41 were variable and parsimony-uninformative and 385 were parsimony-informative. Maximum parsimony analysis yielded 80 equally parsimonious tree (TL = 1,748, CI = 0.4027, HI = 0.5973, RI = 0.6935 and RC = 0.2793). The best model of nucleotide evolution for the ITS dataset estimated and applied in the Bayesian analysis was found to be GTR+I+G. Bayesian analysis and ML analysis resulted in a similar topology as in the MP analysis. The Bayesian analysis had an average standard deviation of split frequencies = 0.014964 (BI) and the effective sample size (ESS) across the two runs is double the average ESS (avg. ESS) = 1,387.5. The phylogenetic tree (Fig. 2), inferred from the ITS sequences, highlighted that *L. hengduanensis* group with *L. zhaotongensis*; and then closely grouped with *L. crustosus* (Pers.) P. Karst., *L. ochraceoalbus* C.L. Zhao and *L. vietnamensis* (Yurchenko & Sheng H. Wu) Riebesehl & Langer. *Lyomyces niveomarginatus* was retrieved as a sister to *L. juniperi* (Bourdot & Galzin) Riebesehl & Langer. *Lyomyces wumengshanensis* was retrieved as a sister to *L. macrosporus* C.L. Zhao. Moreover, *Lyomyces zhaotongensis* grouped with *L. hengduanensis* and closely clustered with *L. crustosus*, *L. ochraceoalbus* and *L. vietnamensis*.

Taxonomy

***Lyomyces hengduanensis* Q. Yuan & C.L. Zhao, sp. nov.**
MycoBank No: 853724
Figs 3, 4

Type material. *Holotype*. China • Yunnan Province, Lincang, Fengqing County, Yaojie Town, GPS coordinates 24°66'N, 100°19'E, altitude 2060 m, on a fallen branch of angiosperm, leg. C.L. Zhao, 22 October 2022, CLZhao 25551 (SWFC).

Etymology. *Hengduanensis* (Lat.) refers to the type locality "Hengduan Mountain".

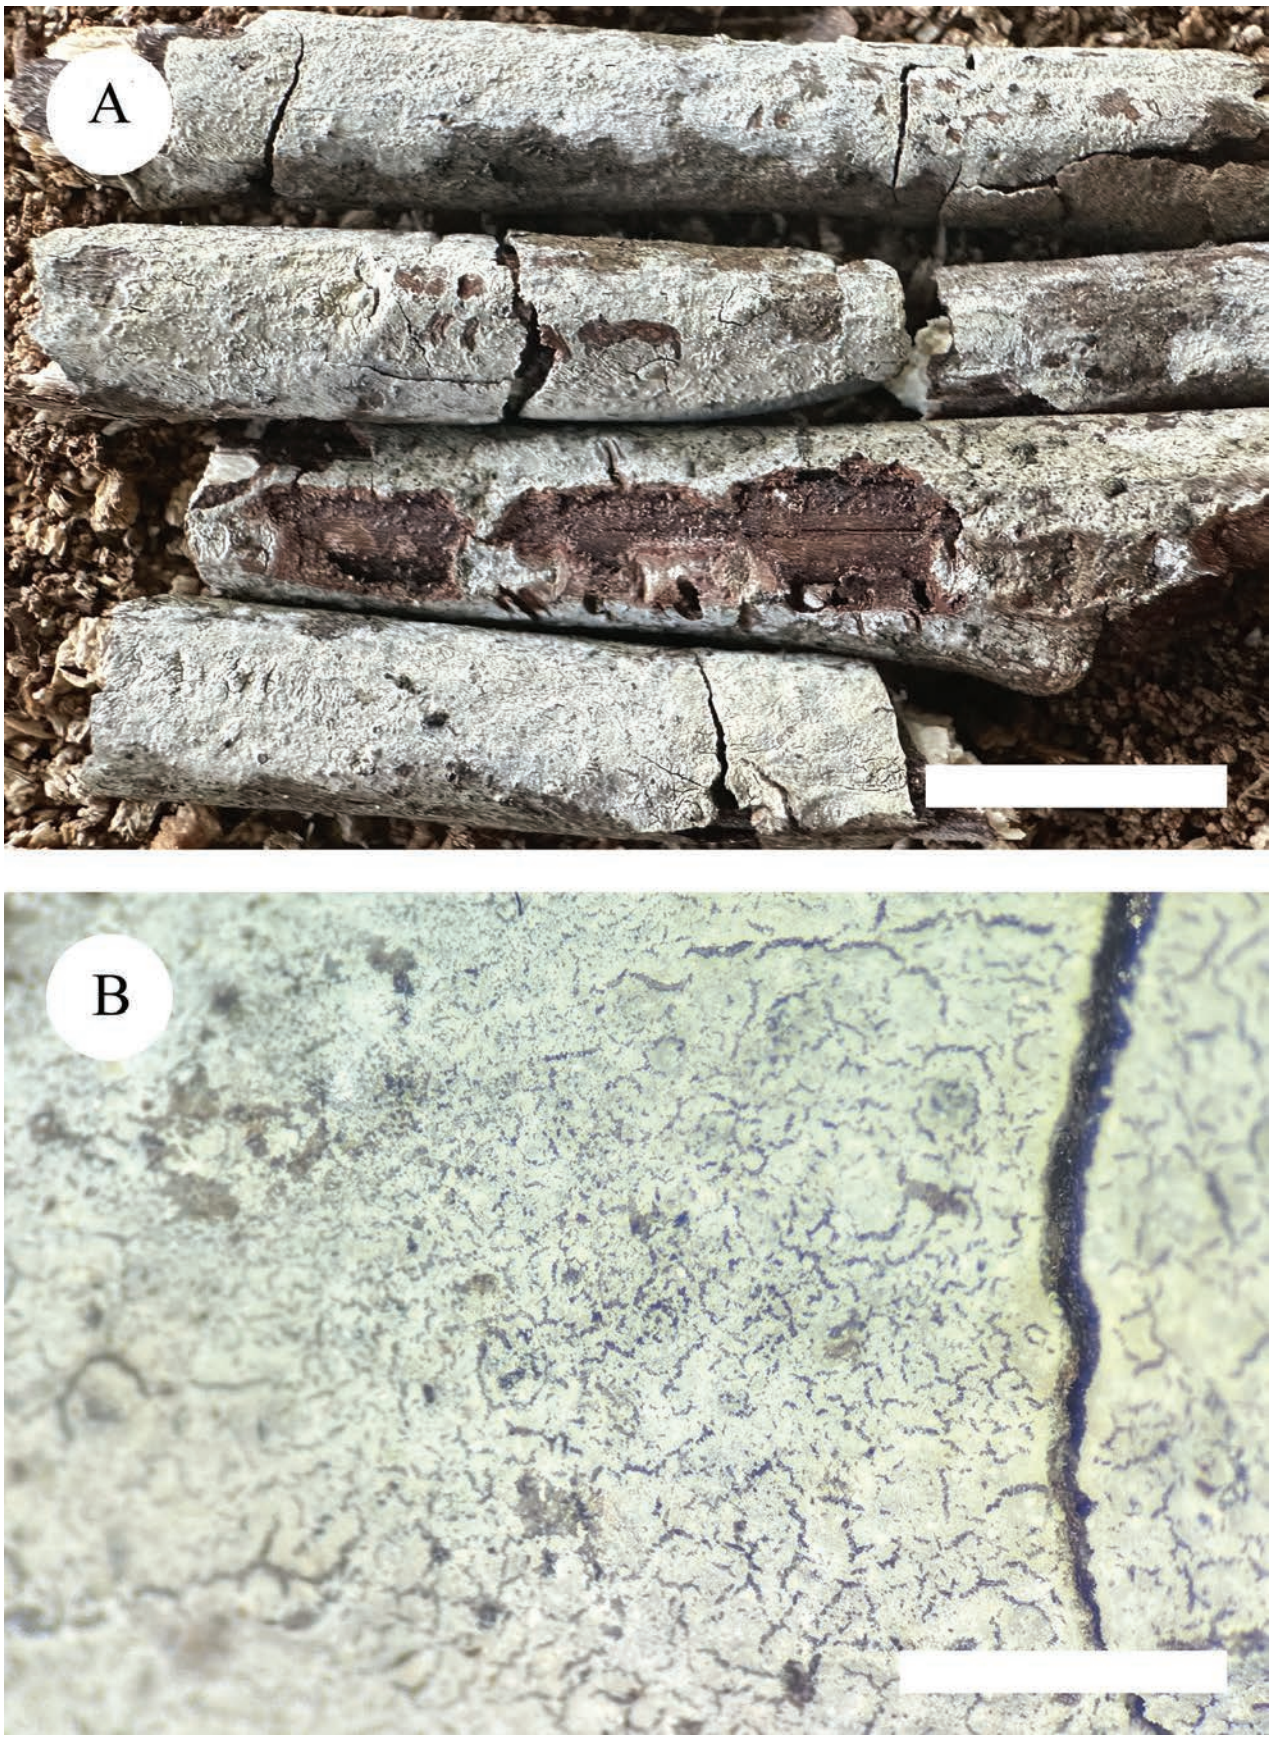

Figure 3. Basidiomata of *Lyomyces hengduanensis* (holotype). Scale bars: 1 cm (**A**); 2 mm (**B**).

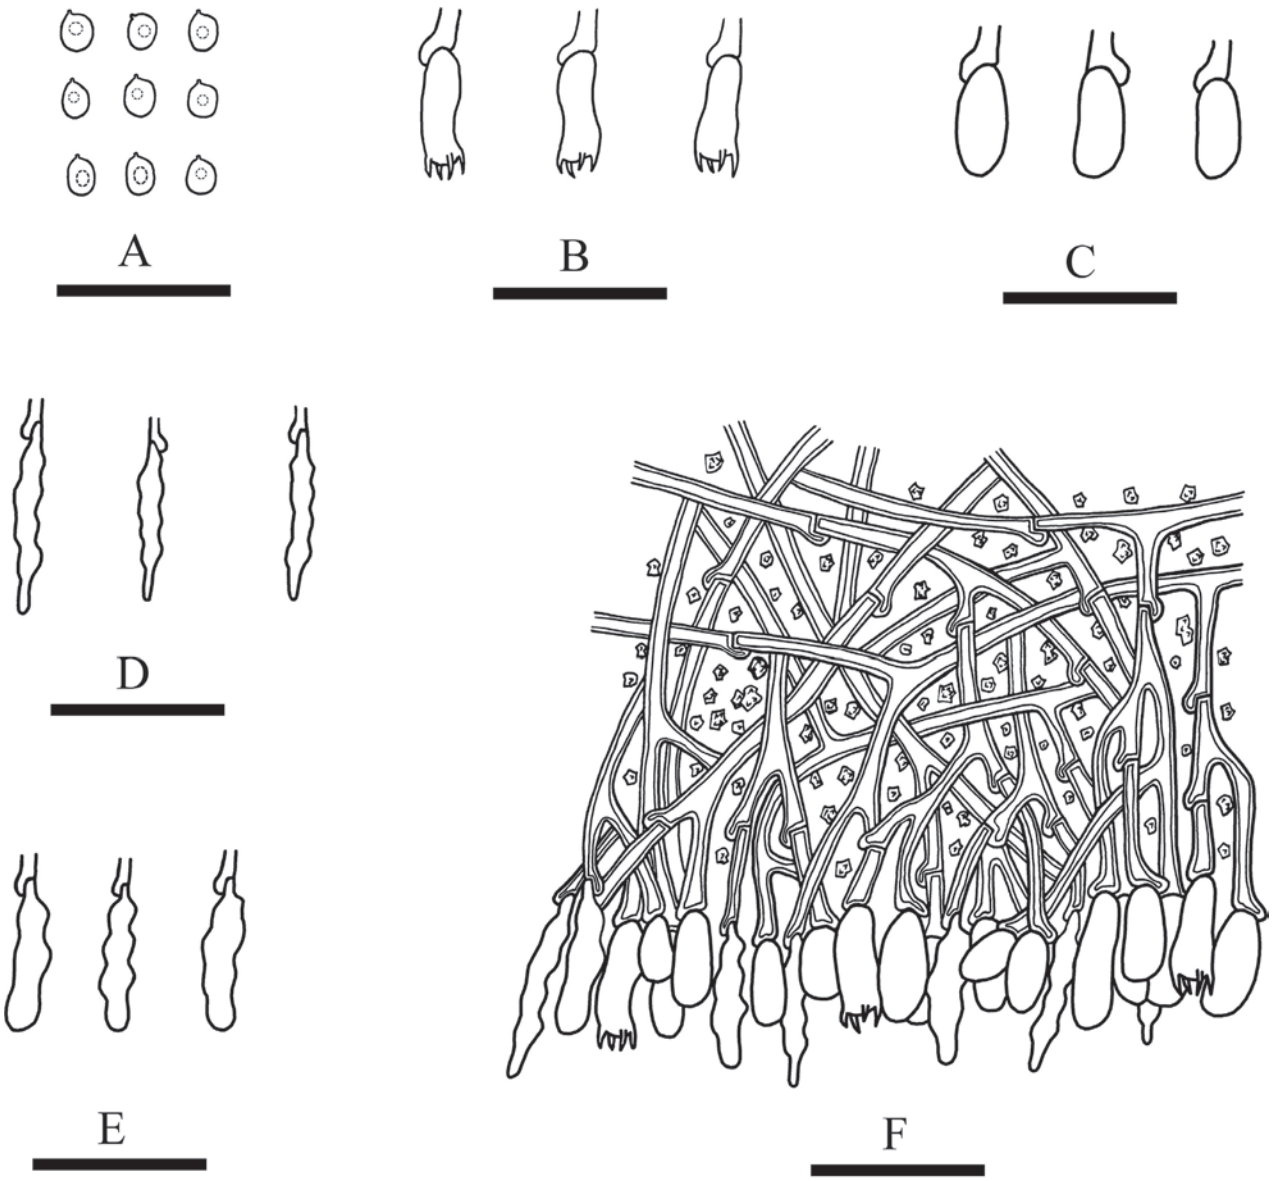

Figure 4. Microscopic structures of *Lyomyces hengduanensis* (holotype): basidiospores (**A**), basidia (**B**), basidioles (**C**), fusoid cystidia (**D**), subclavate cystidia (**E**), a section of hymenium (**F**). Scale bars: 20 μm (**A–F**).

Description. Basidiomata annual, resupinate, adnate, brittle, without odour and taste when fresh and up to 3.5 cm long, 1 cm wide, 100 μm thick. Hymenial surface pruinose, white to cream when fresh, to cream to slightly buff upon drying. Sterile margin white to cream and up to 1 mm wide.

Hyphal system monomitic, generative hyphae with clamp connections, colourless, thick-walled, branched, 2–3 μm in diameter; IKI–, CB–, tissues unchanged in KOH. Numerous crystals present amongst generative hyphae.

Cystidia of two types: (1) fusoid, colourless, thin-walled, smooth, slightly constricted in the middle to somewhat sinuous, 17.5–25 × 3–4 μm; (2) subclavate, colourless, thin-walled, smooth, slightly constricted in the middle to somewhat sinuous, 16–23 × 3–4.5 μm; basidia clavate, with 4 sterigmata and a basal clamp connection, 10.5–14 × 3.5–5 μm.

Basidiospores ellipsoid, colourless, thin-walled, smooth, with one oil drop, CB–, IKI–, 3.5–6 × 3–4.5 µm, L = 4.63 µm, W = 3.65 µm, Q = 1.25–1.28 (n = 90/3).

Additional specimens examined (*paratypes*). China • Yunnan Province, Zhaotong, Qiaojia County, Yaoshan Town, Yaoshan National Nature Reserve, 26°50'N, 102°59'E, altitude 2500 m, on a fallen branch of angiosperm, leg. C.L. Zhao, 22 August 2020, CLZhao 20627 (SWFC) • Zhaotong, Wumeng Mountain National Nature Reserve, GPS coordinates 27°72'N, 103°92'E, altitude 1424 m, on a fallen branch of angiosperm, leg. C.L. Zhao, 29 August 2023, CLZhao 32713, CLZhao 32714, CLZhao 32782 (SWFC).

***Lyomyces niveomarginatus* Q. Yuan & C.L. Zhao, sp. nov.**

MycoBank No: 853725

Figs 5, 6

Type material. *Holotype*. China • Yunnan Province, Wenshan, Wenshan National Nature Reserve, GPS coordinates 23°21'N, 104°10'E, altitude 1950 m, on a fallen branch of angiosperm, leg. C.L. Zhao, 26 July 2019, CLZhao 16360 (SWFC).

Etymology. *Niveomarginatus* (Lat.) refers to the niveous margin of basidiomata.

Description. Basidiomata annual, resupinate, adnate, subceraceous, without odour and taste when fresh and up to 7.5 cm long, 2 cm wide, 150 µm thick. Hymenial surface crackled, white to cream when fresh, to cream to slightly buff upon drying. Sterile margin distinct, whitish and up to 2 mm wide.

Hyphal system monomitic, generative hyphae with clamp connections, colourless, thin-walled, branched, 1.5–3.5 µm in diameter; IKI–, CB–, tissues unchanged in KOH. Numerous crystals present amongst generative hyphae.

Cystidia of two types: (1) fusoid, colourless, thin-walled, smooth, 25–29 × 2–3 µm; (2) clavate, colourless, thin-walled, smooth, 20–25.5 × 4.5–5.5 µm; basidia subclavate, with 4 sterigmata and a basal clamp connection, 23–29 × 2.5–3.5 µm.

Basidiospores ellipsoid, colourless, thin-walled, smooth, with one oil drop, CB–, IKI–, 4.5–7 × (2.5–)3–4 µm, L = 5.51 µm, W = 3.15 µm, Q = 1.75 (n = 30/1).

Additional specimens examined (*paratypes*). China • Yunnan Province, Wenshan, Wenshan National Nature Reserve, GPS coordinates 23°21'N, 104°10'E, altitude 1950 m, on a fallen branch of angiosperm, leg. C.L. Zhao, 7 August 2024, CLZhao 40333, CLZhao 40334 (SWFC).

***Lyomyces wumengshanensis* Q. Yuan & C.L. Zhao, sp. nov.**

MycoBank No: 853726

Figs 7, 8

Type material. *Holotype*. China • Yunnan Province, Zhaotong, Daguan County, Wumeng Mountain National Nature Reserve, GPS coordinates 27°72'N, 103°92'E, altitude 1424 m, on a fallen branch of angiosperm, leg. C.L. Zhao, 3 July 2023, CLZhao 29374 (SWFC).

Etymology. *Wumengshanensis* (Lat.) refers to the type locality "Wumeng Mountain".

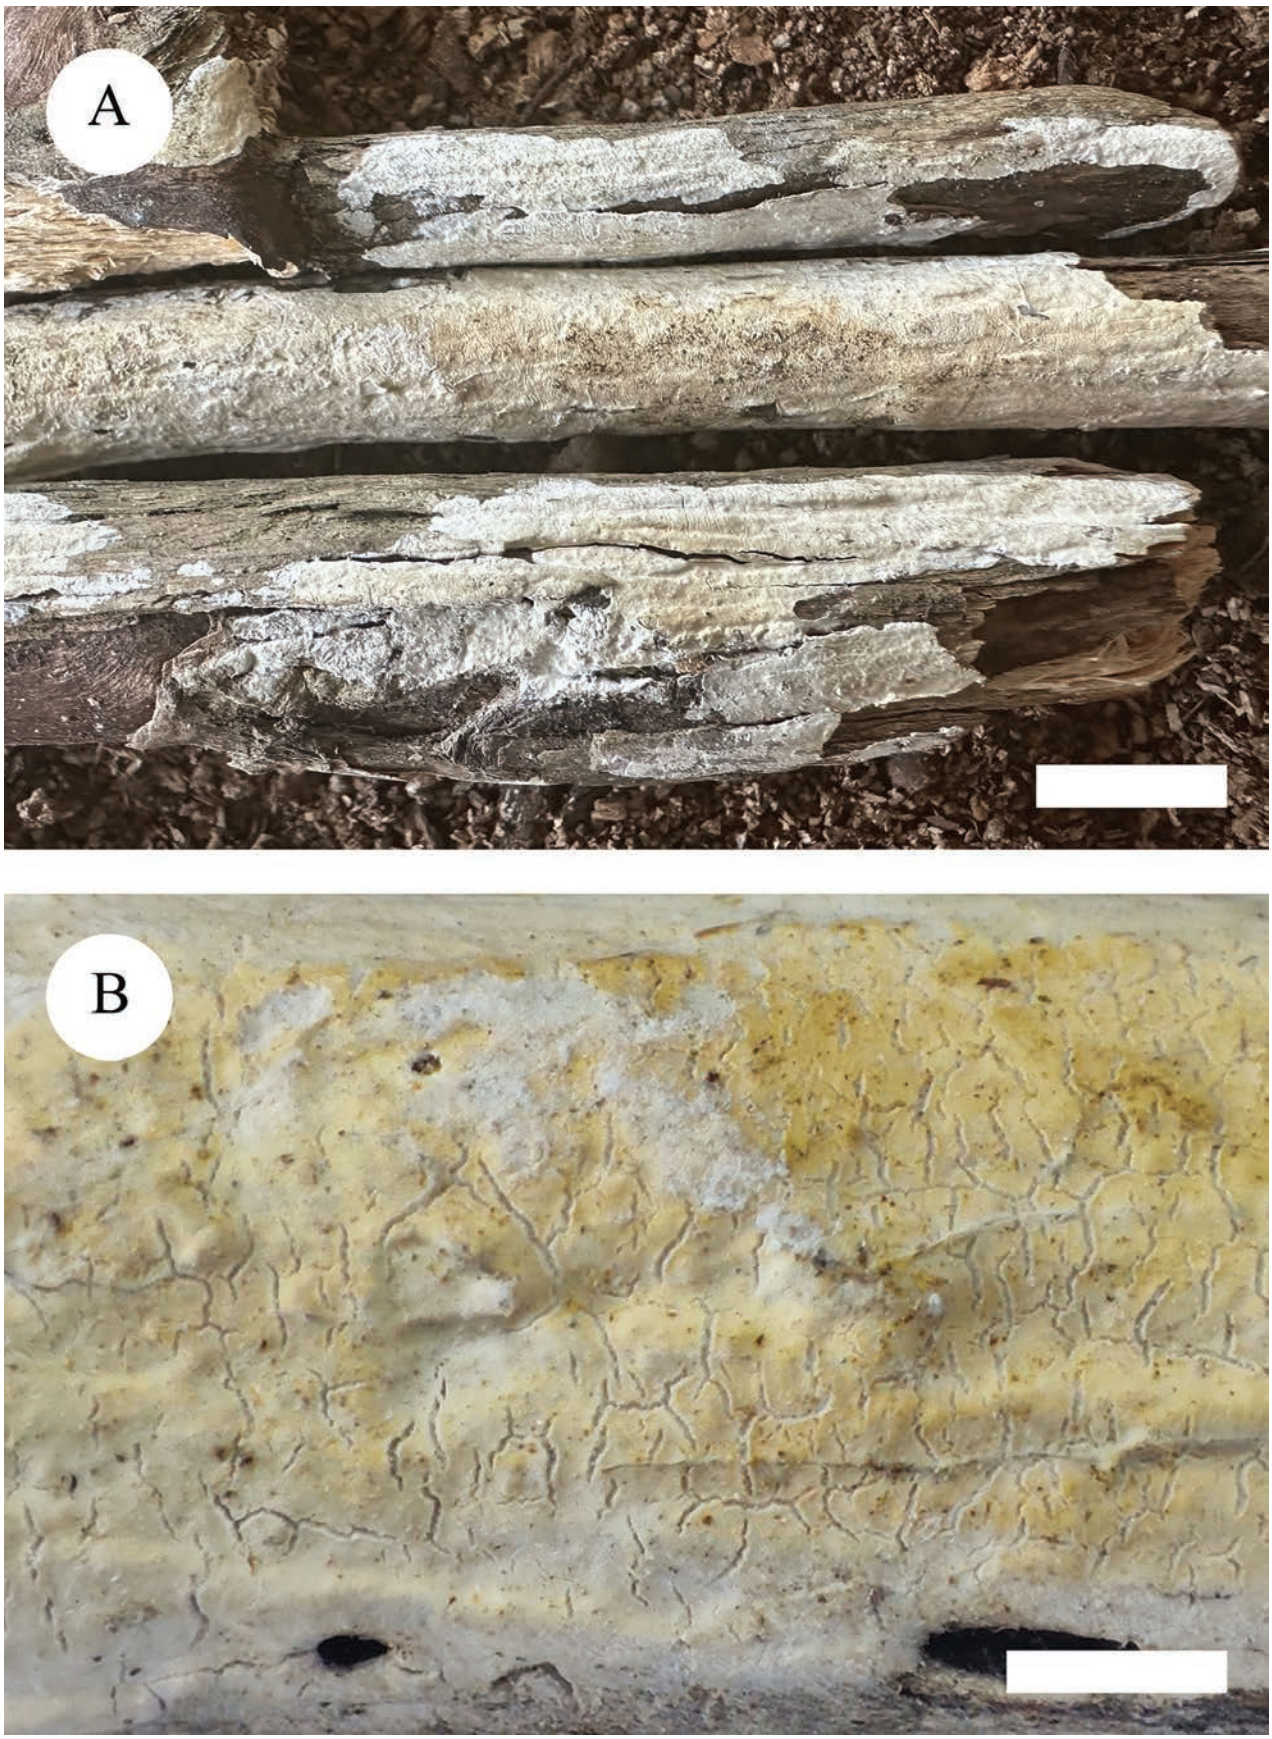

Figure 5. Basidiomata of *Lyomyces niveomarginatus* (holotype). Scale bars: 1 cm (**A**); 2 mm (**B**).

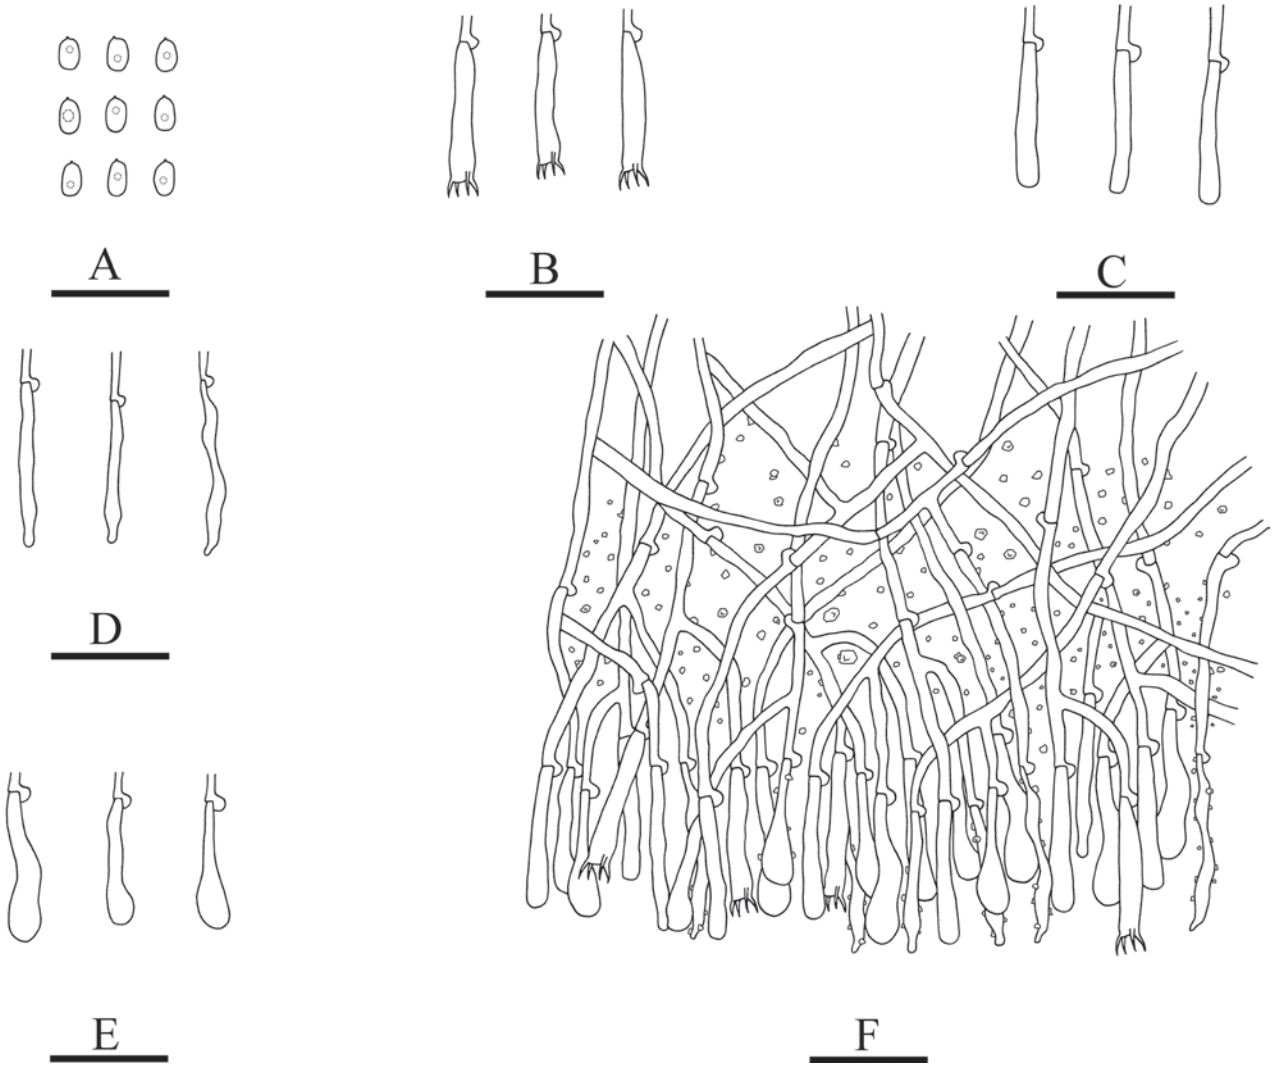

Figure 6. Microscopic structures of *Lyomyces niveomarginatus* (holotype): basidiospores (**A**), basidia (**B**), basidioles (**C**), fusoid cystidia (**D**), clavate cystidia (**E**), a section of hymenium (**F**). Scale bars: 20 μm (**A–F**).

Description. Basidiomata annual, resupinate, adnate, coriaceous when fresh, becoming farinaceous upon drying, without odour and taste when fresh and up to 5 cm long, 2 cm wide, 150 μm thick. Hymenial surface grandinioid, white when fresh, to cream upon drying. Sterile margin white and up to 1 mm wide.

Hyphal system monomitic, generative hyphae with clamp connections, colourless, thick-walled, branched, 3–4 μm in diameter; IKI–, CB–, tissues unchanged in KOH. Numerous crystals present amongst generative hyphae.

Cystidia capitate, colourless, thin-walled, smooth, 24.5–29 × 3–4 μm; basidia subclavate to barrelled, colourless, with 4 sterigmata and a basal clamp connection, 11.5–14 × 5.5–6.5 μm.

Basidiospores ellipsoid to broad ellipsoid, colourless, thin-walled, smooth, with one oil drop, CB–, IKI–, 4–6 × 3–5 μm, L = 5.4 μm, W = 4.2 μm, Q = 1.28–1.32 (n = 120/4).

Additional specimen examined (*paratype*). China • Yunnan Province, Zhaotong, Wumeng Mountain National Nature Reserve, 27°72'N, 103°92'E, altitude 1424 m, on a fallen branch of angiosperm, leg. C.L. Zhao, 29 August 2023, CLZ-

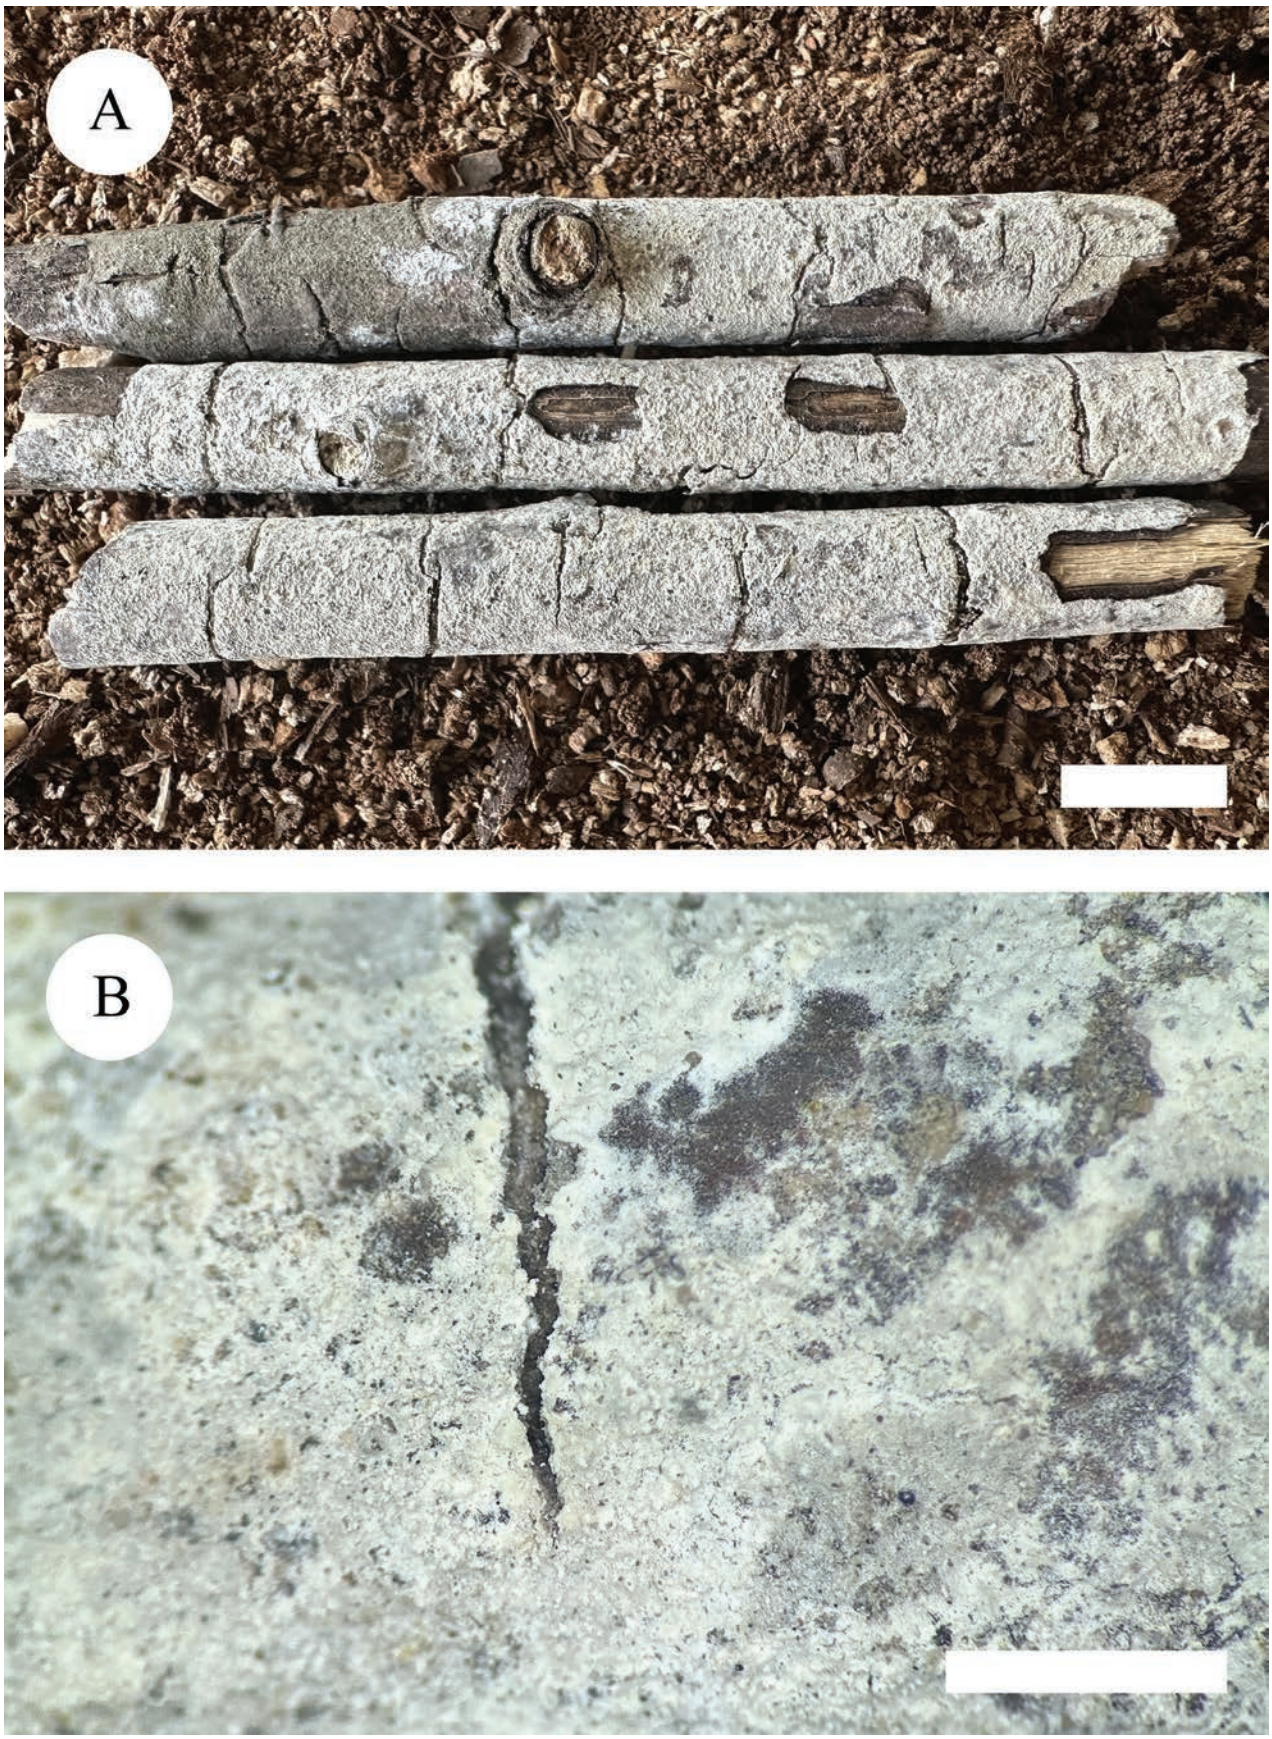

Figure 7. Basidiomata of *Lyomyces wumengshanensis* (holotype). Scale bars: 1 cm (**A**); 2 mm (**B**).

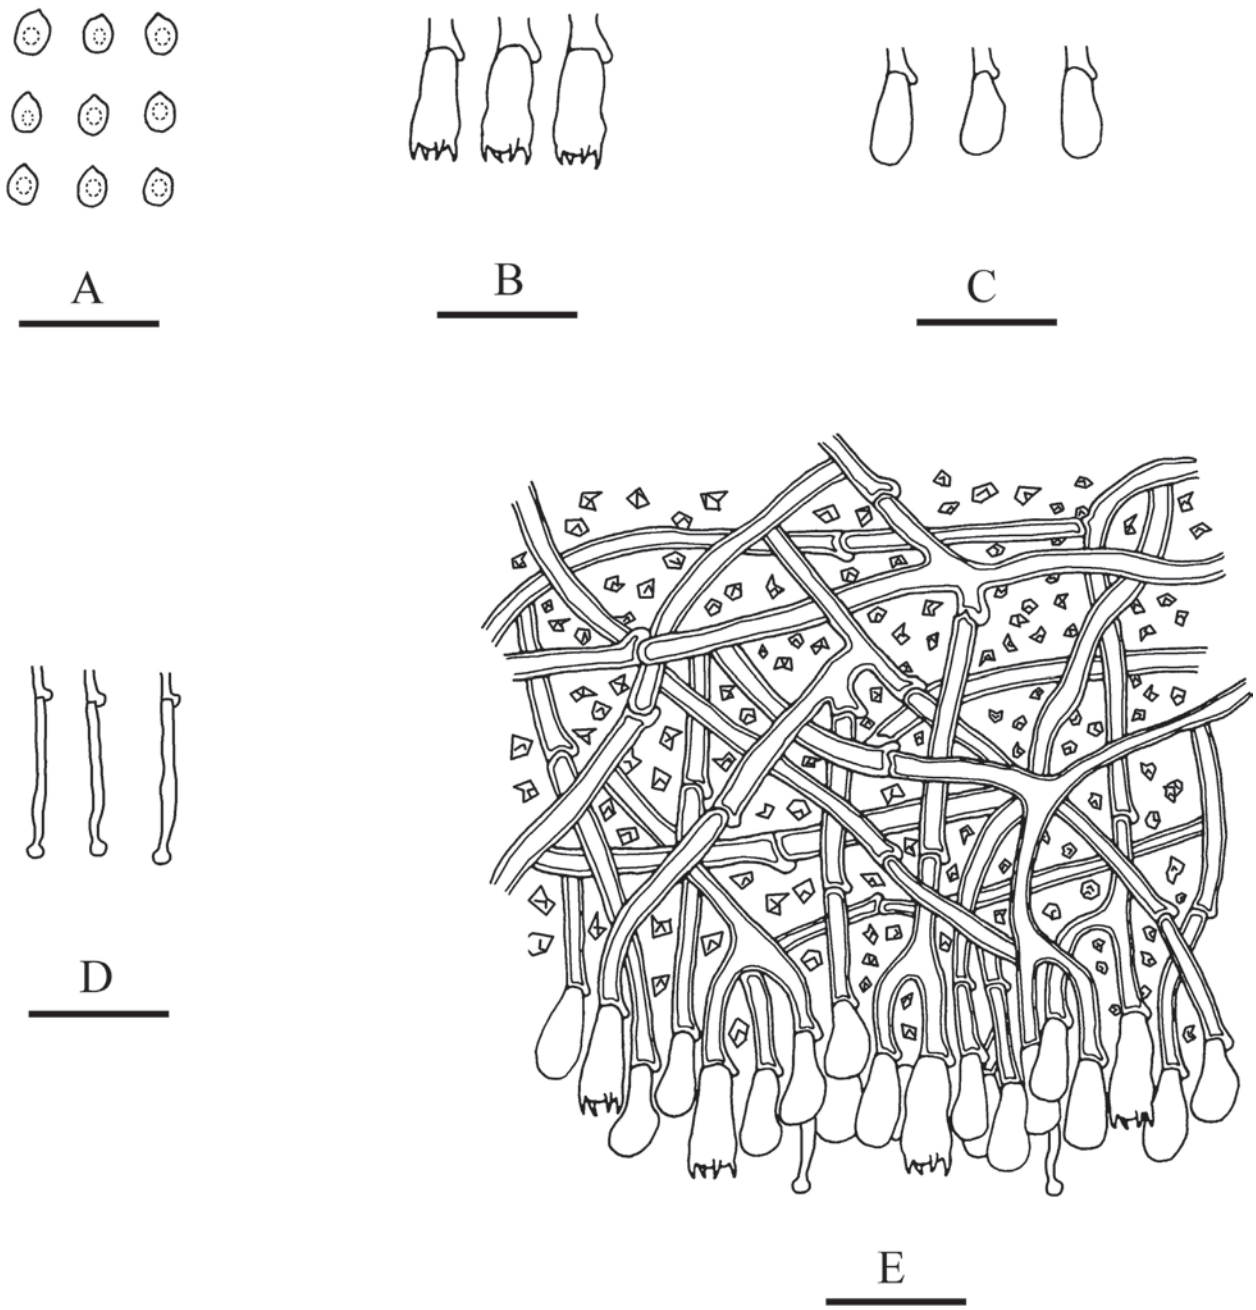

Figure 8. Microscopic structures of *Lyomyces wumengshanensis* (holotype): basidiospores (**A**), basidia (**B**), basidioles (**C**), capitate cystidia (**D**), a section of hymenium (**E**). Scale bars: 10 μm (**A–E**).

***Lyomyces zhaotongensis* Q. Yuan & C.L. Zhao, sp. nov.**
MycoBank No: 853727
Figs 9, 10

Type material. *Holotype*. China •Yunnan Province, Zhaotong, Wumeng Mountain National Nature Reserve, GPS coordinates 27°77'N, 104°29'E, altitude

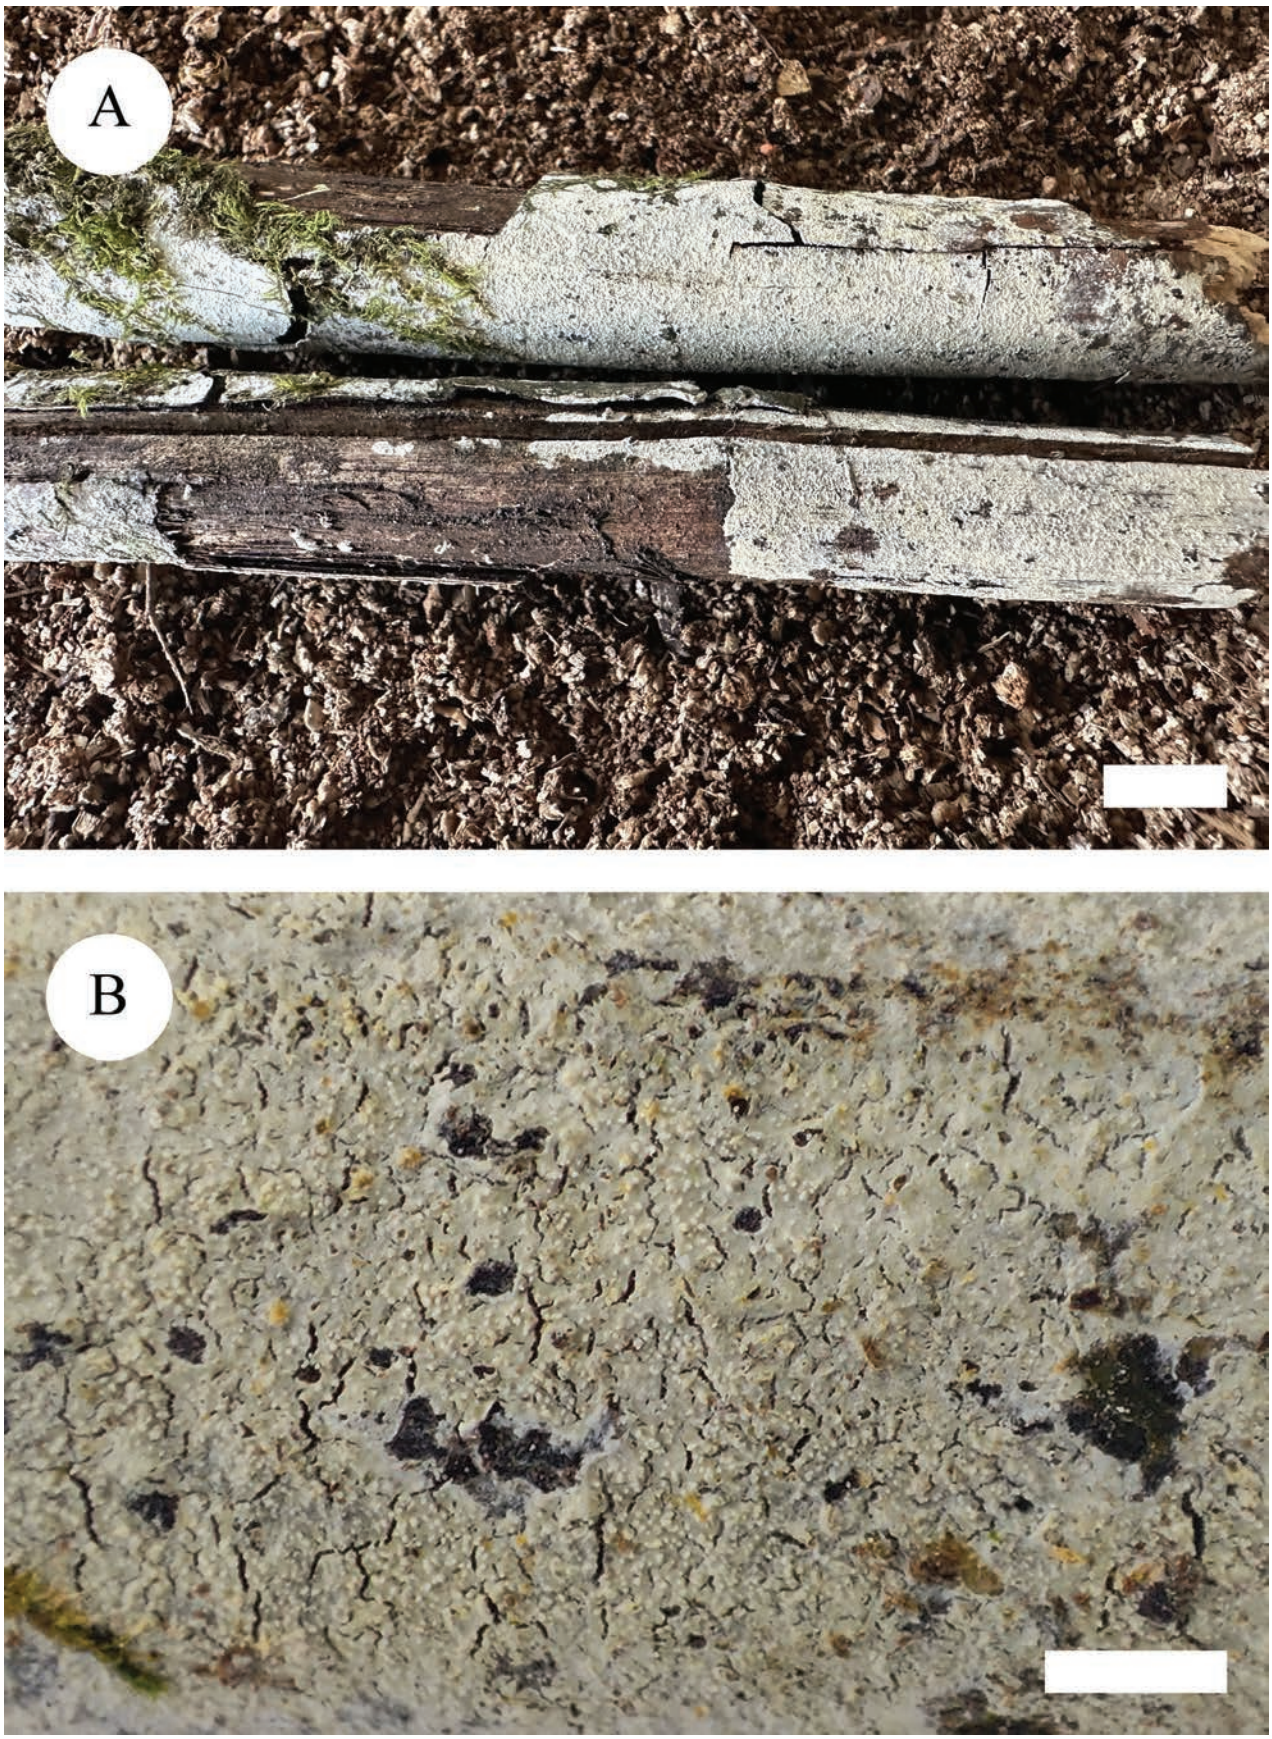

Figure 9. Basidiomata of *Lyomyces zhaotongensis* (holotype). Scale bars: (**A**) 1 cm; (**B**) 2 mm.

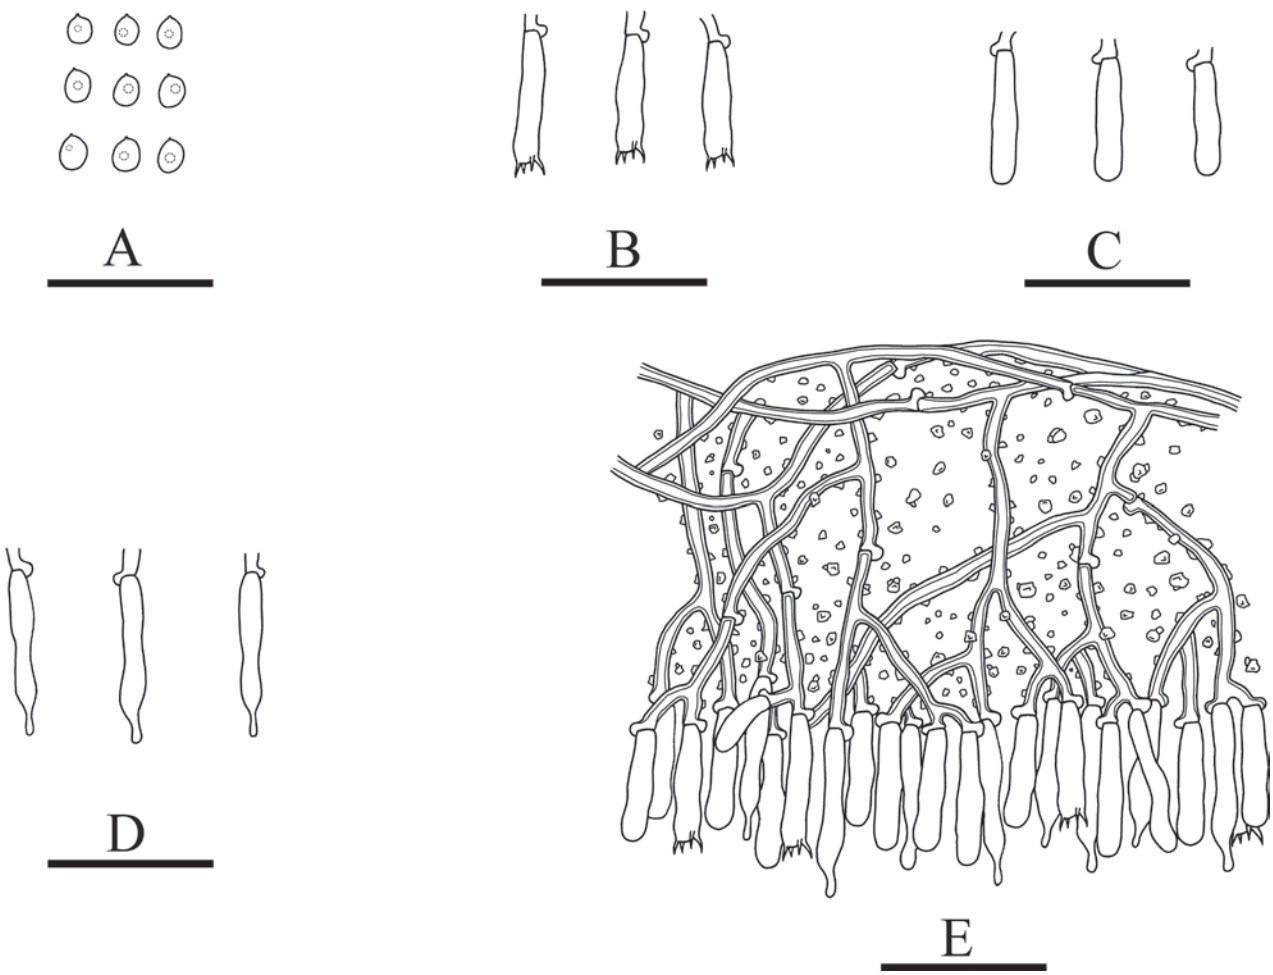

Figure 10. Microscopic structures of *Lyomyces zhaotongensis* (holotype): basidiospores (**A**), basidia (**B**), basidioles (**C**), fusoid cystidia (**D**), a section of hymenium (**E**). Scale bars: 20 μm (**A–E**).

2900 m, on the fallen branch of angiosperm, leg. C.L. Zhao, 29 August 2023, CLZhao 32878 (SWFC).

Etymology. *Zhaotongensis* (Lat.) refers to the type locality "Zhaotong".

Description. Basidiomata annual, resupinate, adnate, farinaceous when fresh, becoming coriaceous upon drying and up to 9.5 cm long, 3 cm wide, 30–80 um thick. Hymenial surface grandinioid, cream when fresh and cream to buff upon drying. Sterile margin white to cream and up to 1 mm wide.

Hyphal system monomitic, generative hyphae with clamp connections, colourless, thick-walled, branched, 1.5–2 μm in diameter; IKI–, CB–, tissues unchanged in KOH. Numerous crystals present amongst generative hyphae.

Cystidia fusoid, colourless, thin-walled, smooth, 16–20.5 × 2.5–3.5 μm. Basidia clavate, with 4 sterigmata and a basal clamp connection, 14–16.5 × 2.5–3.5 μm.

Basidiospores broadly ellipsoid, colourless, thin-walled, smooth, with oil drops, CB–, IKI–, 2.6–3.5 × 2.5–3 μm, L = 2.99 μm, W = 2.75 μm, Q = 1.08 (n = 30/1).

Additional specimen examined (*paratype*). China • Yunnan Province, Zhaotong, Wumeng Mountain National Nature Reserve, GPS coordinates 27°77'N, 104°29'E, altitude 2900 m, on the fallen branch of angiosperm, leg. C.L. Zhao, 10 August 2024, CLZhao 40335 (SWFC).

Discussion

Many recently new wood-inhabiting fungal taxa have been reported in the subtropics and tropics, including in the genus *Lyomyces* (Xiong et al. 2009; Chen et al. 2017; Kan et al. 2017a, b; Riebesehl and Langer 2017; Viner et al. 2018; Chen and Zhao 2020; Luo et al. 2021a, b, c, 2022; Qu and Zhao 2022; Qu et al. 2022; Viner et al. 2022; Guan et al. 2023; Deng et al. 2024a, b; Zhang et al. 2024). Prior to this study, the following sixteen *Lyomyces* species were reported from China as *L. albopulverulentus* C.L. Zhao, *L. albus* (Sheng H. Wu) Riebesehl & Langer, *L. bambusinus*, *L. capitatocystidiatus* (H.X. Xiong, Y.C. Dai & Sheng H. Wu) Riebesehl & Langer, *L. cremeus* C.L. Zhao, *L. fissuratus*, *L. fumosus*, *L. leptocystidiatus* Xue W. Wang & L.W. Zhou, *L. macrosporus* C.L. Zhao & K.Y. Luo, *L. microfasciculatus* (Yurchenko & Sheng H. Wu) Riebesehl & Langer, *L. niveus*, *L. ochraceoalbus*, *L. sambuci*, *L. tenuissimus* (Yurchenko & Sheng H. Wu) Riebesehl & Langer, *L. wuliangshanensis* C.L. Zhao and *L. yunnanensis* C.L. Zhao (Xiong et al. 2009; Yurchenko et al. 2013; Riebesehl and Langer 2017; Chen and Zhao 2020; Luo et al. 2021b, c; Wang et al. 2021). The present study reports four new species in the genus *Lyomyces*, based on a combination of morphological features and molecular evidence.

Phylogenetically, based on the multiple loci in *Hyphodontia* s.l., six genera of *Fasciodontia*, *Hastodontia*, *Hyphodontia*, *Lyomyces*, *Kneiffiella* and *Xylodon*, were divided into four clades in the wood-inhabiting fungal order Hymenochaetales (Wang et al. 2021). In the present study, the phylogram inferred from the ITS+nLSU data, four new species grouped into the genus *Lyomyces* (Fig. 1). Based on ITS topology (Fig. 2), in which *L. hengduanensis* group with *L. zhaotongensis* and then closely grouped with *L. crustosus*, *L. ochraceoalbus* and *L. vietnamensis*. *Lyomyces niveomarginatus* was retrieved as a sister to *L. juniperi*. *L. wumengshanensis* was sister to *L. macrosporus*. Moreover, *L. zhaotongensis* grouped with *L. hengduanensis* and then closely clustered with three species: *L. crustosus*, *L. ochraceoalbus* and *L. vietnamensis*. However, morphologically, *L. zhaotongensis* can be delimited from *L. hengduanensis* by its the grandinioid hymenial surface and longer basidia (14–16.5 × 2.5–3.5 µm); *L. crustosus* can be separated from *L. hengduanensis* by its odontioid hymenial surface and narrow basidiospores (5–7.5 × 2.5–3 µm) (Lentz and McKay 1976); *L. ochraceoalbus* differs in *L. hengduanensis* by having a smooth hymenial surface and lacking a cystidium (Luo et al. 2021c); *L. vietnamensis* differs from *L. hengduanensis* by its aculeate hymenial surface and narrow basidiospores (5.8–6.1 × 2.6–2.9 µm; Yurchenko and Wu (2013)). *L. juniperi* can be delimited from *L. niveomarginatus* by its smooth hymenial surface with some scattered small granules and wider basidia (15–25 × 4–4.5 µm; Hjortstam and Ryvarden (2004)); *L. macrosporus* can be separated from *L. wumengshanensis* by its reticulate hymenial surface and longer basidiospores (6.7–8.9 × 4.4–5.4 µm; Chen and Zhao (2020)); *L. crustosus* can be delimited from *L. zhaotongensis* by its odontioid hymenial surface and longer basidiospores (5–7.5 × 2.5–3 µm; Lentz and McKay (1976)); *L. hengduanensis* can be delimited from *L. zhaotongensis* by its pruinose hymenial surface and shorter basidia (14–16.5 × 2.5–3.5 µm); *L. ochraceoalbus* differs in *L. zhaotongensis* by having smooth hymenial surface and longer basidiospores (4–5 × 2.5–3.5 µm; Luo et al. (2021c)); *L. vietnamensis* can be delimited from *L. zhaotongensis* by its

aculeate hymenial surface and longer basidiospores (5.8–6.1 × 2.6–2.9 µm; Yurchenko and Wu (2013)).

Morphologically, *Lyomyces hengduanensis* resembles four taxa viz. *L. albopulverulentus*, *L. bambusinus*, *L. mascarensis* Riebesehl, Yurch. & Langer and *L. yunnanensis*, by the similar ellipsoid basidiospores. However, *L. albopulverulentus* differs from *L. hengduanensis* by its larger basidia (24.5–28.5 × 7–9 µm) and basidiospores (8–10.5 × 5.5–7 µm; Guan et al. (2023)); *L. bambusinus* can be separated from *L. hengduanensis* by its colliculose to tuberculate hymenial surface and longer basidia (16.5–35 × 3.5–7 µm; Chen and Zhao (2020)); *L. mascarensis* is distinct from *L. hengduanensis* by having indistinctly colliculose hymenial surface and longer basidia (16–17.5 × 3.5–4.5 µm; Yurchenko et al. (2017)); *L. yunnanensis* is distinguished from *L. hengduanensis* by its grandinioid hymenial surface and longer basidia (16.5–27 × 4–5.5 µm; Guan et al. (2023)).

Morphologically, *Lyomyces niveomarginatus* resembles several species viz. *L. albopulverulentus*, *L. cremeus*, *L. macrosporus*, *L. wuliangshanensis* and *L. yunnanensis* by the cream to buff hymenial surface and ellipsoid basidiospores. However, *L. albopulverulentus* differs from *L. niveomarginatus* by its pruinose hymenial surface and wider basidia (24.5–28.5 × 7–9 µm; Guan et al. (2023)); *L. cremeus* can be separated from *L. niveomarginatus* by its smooth hymenial surface and shorter basidia (9–18.5 × 3–6 µm; Chen and Zhao (2020)); *L. macrosporus* differs from *L. niveomarginatus* by its reticulate hymenial surface and wider basidia (23–29 × 2.5–3.5 µm) and wider basidiospores (6.7–8.9 × 4.4–5.4 µm; Chen and Zhao (2020)); *L. wuliangshanensis* can be delimited from *L. niveomarginatus* by its smooth to more or less tuberculate hymenial surface and shorter basidia (12–20 × 3–4.3 µm; Chen and Zhao (2020)); *L. yunnanensis* is distinct from *L. niveomarginatus* by having grandinioid hymenial surface and wider basidia (16.5–27 × 4–5.5 µm; Guan et al. (2023)).

Morphologically, *Lyomyces wumengshanensis* resembles *L. bambusinus*, *L. cremeus*, *L. fumosus*, *L. fissuratus*, *L. wuliangshanensis* and *L. yunnanensis* by having the capitate cystidia. However, *L. bambusinus* is distinct from *L. wumengshanensis* by possessing tapering cystidia (40–65 × 4–5.5 µm) and longer basidia (16.5–35 × 3.5–7 µm; Chen and Zhao (2020)); *L. cremeus* differs from *L. wumengshanensis* by its smooth hymenial surface and possesses tapering cystidia (18–35 × 3–4.5 µm; Chen and Zhao (2020)); *L. fumosus* can be separated from *L. wumengshanensis* by its smooth, smoky grey hymenial surface and narrower basidia (11.5–17.5 × 3–5 µm; Luo et al. (2021b)); *L. fissuratus* can be delimited from *L. wumengshanensis* by its longer and narrower basidia (14.7–23.3 × 2.9–4.8 µm; Luo et al. (2021b)); *L. wuliangshanensis* differs from *L. wumengshanensis* by its smooth to more or less tuberculate hymenial surface and narrower basidia (12–20 × 3–4.3 µm; Chen and Zhao (2020)); *L. yunnanensis* is separated from *L. wumengshanensis* by the longer basidia (16.5–27 × 4–5.5 µm) and possessing fusiform cystidia (18–39 × 4–6 µm; Guan et al. (2023)).

Morphologically, *Lyomyces zhaotongensis* reminds *L. albopulverulentus*, *L. cremeus*, *L. denudatus* Viner, *L. macrosporus* and *L. wuliangshanensis* by having the ellipsoid basidiospores. However, *L. albopulverulentus* can be separated from *L. zhaotongensis* by its pruinose hymenial surface and larger basidia (24.5–28.5 × 7–9 µm) and larger basidiospores (8–10.5 × 5.5–7 µm; Guan et al. (2023)); *L. cremeus* is distinct from *L. zhaotongensis* by its smooth hymenial surface and larger basidiospores (4.5–5.6 × 3.3–4.3 µm; Chen and Zhao

(2020)); *L. denudatus* is separated from *L. zhaotongensis* by the smooth hymenial surface and longer basidiospores (4.8–7 × 2.8–4.2 µm; Viner and Miettinen (2022)); *L. macrosporus* differs from *L. zhaotongensis* due to its reticulate hymenial surface and larger basidia (22.2–38 × 4.5–7 µm) and larger basidiospores (6.7–8.9 × 4.4–5.4 µm; Chen and Zhao (2020)); *L. wuliangshanensis* can be delimited from *L. zhaotongensis* by its smooth to more or less tuberculate hymenial surface and longer basidiospores (3.5–5.3 × 2.8–4 µm; Chen and Zhao (2020)). A morphological comparison amongst four new *Lyomyces* species and seven similar species are presented in Table 2.

The Basidiomycota is a major phylum of the kingdom Fungi (He et al. 2019; Wijayawardene et al. 2020; Yuan et al. 2023; He et al. 2024), in which the wood-inhabiting fungi are an extensively studied group of Basidiomycota (Gilbertson and Ryvarden 1987; Bernicchia and Gorjón 2010; Núñez and Ryvarden 2001; Dai 2012; Ryvarden and Melo 2014; Wu et al. 2022b; Zhao et al. 2023; Dong et al. 2024), but the wood-inhabiting fungal diversity is still not well known in China, especially in subtropical and tropical areas, and many recently-described taxa of this ecologically important group were from China (Zhao et al. 2014; Zhao et al. 2015; Zhao et al. 2016; Bian et al. 2016; Ma and Zhao 2019; Guan et al. 2020; Huang and Zhao 2020; Guan et al. 2023; Ji et al. 2023; Liu et

Table 2. A morphological comparison between four new *Lyomyces* species and seven similar species in the genus *Lyomyces*. The bold are new taxa.

Species name	Hymenial surface	Generative hyphae	Cystidia	Basidia	Basidiospores	References
Lyomyces albopulverulentus	Pruinose/ white	Thick-walled/ frequently branched	Capitate, 37–54 × 5–9 µm	Clavate, 24.5–28.5 × 7–9 µm	Ellipsoid, (7.5–)8–10.5(–11) × (5–)5.5–7 µm	Guan et al. (2023)
Lyomyces bambusinus	Colliculose to tuberculate/ cream to buff	Thick-walled/ branched	Capitate, 35–55 × 4–7 µm; tapering, 40–65 × 4–5.5 µm, cystidioles, 12–17 × 2–3 µm	Clavate, 16.5–35 × 3.5–7 µm	Broadly ellipsoid, (4.5–)4.7–5.9 (–6.2) × (3.4–)3.7–4.6(–4.8) µm	Chen and Zhao (2020)
Lyomyces cremeus	Smooth/ pale cream	Thick-walled/ branched	Capitate, 20–40 × 3–5 µm; tapering, 18–35 × 3–4.5 µm	Clavate, 9–18.5 × 3–6 µm	Ellipsoid, 4.5–5.6(–5.8) × 3.3–4.3(–4.5) µm	Chen and Zhao (2020)
Lyomyces denudatus	Smooth/ cream	Thin-walled to slightly thick-walled	Capitate, (21–)34.9–62 × (3.5–)4–5.5(–7) µm	Suburniform, 15–21.1(–25) × 3.8–5.5 µm	Ellipsoid, (4.1–)4.8–7 × 2.8–4.2(–4.7) µm	Viner and Miettinen (2022)
Lyomyces hengduanensis	Pruinose/ cream to slightly buff	Thick-walled/ branched	Fusoid, 17.5–25 × 3–4 µm; subclavate, 16–23 × 3–4.5 µm	Clavate, 10.5–14 × 3.5–5 µm	Ellipsoid, 3.5–6 × 3–4.5 µm	**Present study**
Lyomyces mascarensis	Smooth / cream or brownish	Thin-walled	Capitate, 17–38 × 3.5–6(–7) µm; submoniliform, 18–22 × 5–5.5 µm; tapering, 25–30 × 3.5–4.5 µm	Subcylindrical with one constriction, 16–17.5(–19) × 3.5–4.5(–6) µm	Ellipsoid or broadly ellipsoid, (4–)4.5–6 × (3–)3.3–4 µm	Yurchenko et al. (2017)
Lyomyces niveomarginatus	Smooth / cream to slightly buff	Thin-walled, branched	Fusoid, 25–29 × 2–3 µm; clavate, 20–25.5 × 4.5–5.5 µm	Subclavate, 23–29 × 2.5–3.5 µm	Ellipsoid, 4.5–7 × (2.5–)3–4 µm	**Present study**
Lyomyces wuliangshanensis	Tuberculate/ cream to buff	Thick-walled/ branched	Capitate, 22–37 × 3–6 µm; tapering, 21–35 × 4–6.5 µm	Clavate, 12–20 × 3–4.3 µm	Ellipsoid, (3.3–)3.5–5.3(–5.5) × 2.8–4(–4.2) µm	Chen and Zhao (2020)
Lyomyces wumengshanensis	Grandinioid/ white to cream	Thick-walled/ branched	Capitate, 24.5–29 × 3–4 µm	Subclavate to barreled, 11.5–14 × 5.5–6.5 µm	Ellipsoid to broad ellipsoid, 4–6 × 3–5 µm	**Present study**
Lyomyces yunnanensis	Grandinioid/ cream to buff	Thick-walled, frequently branched	Tapering, 18–39 × 4–6 µm; capitate, 16–23.5 × 3–5 µm	Clavate, 16.5–27 × 4–5.5 µm	Ellipsoid, (4.5–)5–7 × 3–4.5 µm	Guan et al. (2023)
Lyomyces zhaotongensis	Grandinioid/ cream to buff	Thick-walled/ branched	Fusoid, 16–20.5 × 2.5–3.5 µm	Clavate, 14–16.5 × 2.5–3.5 µm	Broadly ellipsoid, 2.6–3.5 × 2.5–3 µm	**Present study**

al. 2023; Yang et al. 2023; Deng et al. 2024a, b; Yang et al. 2024; Zhang et al. 2024; Zhou et al. 2024). Four new species in the present study are described, based on morphological and molecular phylogenetic analyses, also from the subtropics. This study enriches the wood-inhabiting fungal diversity in China and the world.

Additional information

Conflict of interest

The authors have declared that no competing interests exist.

Ethical statement

No ethical statement was reported.

Funding

The research was supported by the National Natural Science Foundation of China (Project No. 32170004, U2102220), Forestry Innovation Programs of Southwest Forestry University (Grant No: LXXK-2023Z07), the High-level Talents Program of Yunnan Province (YNQR-QNRC-2018-111).

Author contributions

Conceptualization, C.Z.; methodology, C.Z. and Q.Y.; software, C.Z.; validation, C.Z.and Q.Y.; formal analysis, C.Z. and Q.Y.; investigation, C.Z., Q.Y., Y.D. Y.L., K.W. and Y.W.; resources, C.Z.; writing—original draft preparation, C.Z. and Q.Y.; writing—review and editing, C.Z. and Q.Y.; visualization, C.Z. and Q.Y.; supervision, C.Z.; project administration, C.Z.; funding acquisition, C.Z. All authors have read and agreed to the published version of the manuscript.

Corresponding author: Quan Lu (luquan@caf.ac.cn)

Abstract

Climate change has exacerbated outbreaks of forest pests worldwide. In recent years, bark beetles have caused significant damage to coniferous forests of the Northern Hemisphere. *Polygraphus* bark beetles are widely distributed secondary pests. Recently, tree mortality caused by these beetles on the Qinghai-Tibet Plateau has been increasing; however, few studies have focused on their fungal associations. In the present study, we explored the diversity of ophiostomatalean fungi associated with these beetles on the north-eastern and southern Qinghai-Tibet Plateau. We isolated 442 ophiostomatalean strains from adult beetles and their fresh galleries, specifically targeting *Polygraphus poligraphus* and *Polygraphus rudis* infesting *Picea crassifolia* and/or *Pinus griffithii*. Based on phylogenetic and morphological features, we assigned the 442 strains to 16 species belonging to *Grosmannia* spp., *Leptographium* spp. and *Ophiostoma* spp. Amongst these, *Ophiostoma maixiuense* and *Ophiostoma bicolor* were the most frequently isolated species, accounting for 20.8% and 18.1% of the total number of ophiostomatalean assemblages, respectively. By comparing their fungal communities, we found that the different patterns of fungal assemblages of bark beetles from the north-eastern and southern Qinghai-Tibet Plateau may be influenced by biogeographic barriers and host tree species. The results of this study enhance our understanding of bark beetle fungal assemblages, especially *Polygraphus*, on the Qinghai–Tibet Plateau, with implications for forest management under changing climate.

Key words: Conifer, forest pest, *Grosmannia*, *Leptographium*, *Ophiostoma*, pine, spruce, symbiosis

Introduction

Extreme heat and frequent droughts driven by climate change have exacerbated forest pest outbreaks (Biedermann et al. 2019). Recently, bark beetles have inflicted severe damage on coniferous forests across the Northern Hemisphere. In Europe, *Ips typographus* continues to devastate spruce forests, while the frequency of *Ips acuminatus* outbreaks has increased, leading to significant pine tree mortality (Popkin 2021; Papek et al. 2024). A similar trend has been

observed in North America, where elevated temperatures have removed climatic barriers, enabling the northward spread of the aggressive beetles *Dendroctonus frontalis* and *Dendroctonus ponderosae*, which now threaten additional pine forest species and regions (Bentz and Jönsson 2015; Lesk et al. 2017). In China, the Qinghai-Tibet Plateau has not been spared from bark beetle infestations, with species such as *Dendroctonus*, *Ips* and *Polygraphus* causing significant damage (Yin et al. 2016; Wang et al. 2021, 2023). There is growing evidence that fungal symbionts play a crucial role in the ability of bark beetles to respond to climate change and cause tree mortality (Netherer et al. 2021). Despite this, the fungal communities associated with some of these beetles remain poorly understood.

Ophiostomatoid fungi, the most well-known fungal partners of bark beetles, belong to the orders Ophiostomatales (Sordariomycetidae, Sordariomycetes, Ascomycota) and Microascales (Hypocreomycetidae, Sordariomycetes, Ascomycota) (De Beer et al. 2013). Amongst these, the Ophiostomatales is the most diverse group associated with bark beetles, with over 300 species reported across 20 genera (De Beer et al. 2022). The genera *Ophiostoma*, *Leptographium* and *Grosmannia* are particularly notable for their species diversity, close symbiotic relationships with insect vectors and inclusion of species that act as virulent pathogens in host trees. *Ophiostoma* is an ancient genus first described by Sydow and Sydow (1919) and its taxonomy has undergone considerable revision since then. Advances in DNA-based taxonomy and the implementation of the "one fungus, one name" nomenclature have clarified the taxonomic status of this genus. Zipfel et al. (2006) demonstrated that *Ceratocystiopsis* and *Grosmannia* are distinct from *Ophiostoma*, based on multi-gene phylogenies of ribosomal DNA and β-tubulin sequences. Subsequently, *Sporothrix*, which was previously considered part of *Ophiostoma*, was recognised as a separate genus, based on four-gene phylogenies and *sporothrix*-like asexual morphs (De Beer et al. 2016). The taxonomic boundaries between *Grosmannia* and *Leptographium* were historically blurred, but new species in the *Grosmannia penicillata* complex were later described under the genus *Grosmannia* (De Beer and Wingfield 2013; Yin et al. 2020). Today, these two genera are clearly distinguished, based on genome-wide sequence data (de Beer et al. 2022). Additionally, *Heinzbutinia*, *Jamesreidia* and *Masuyamyces* have been recognised as distinct from *Ophiostoma*. The current taxonomic framework for ophiostomatalean fungi, which is considered the most authoritative, defines *Ophiostoma*, *Leptographium* and *Grosmannia* as comprising six complexes and four groups, eight complexes and two groups and two complexes and one group, respectively (De Beer et al. 2022).

Many ophiostomatoid fungi have been shown to play a positive role in the success of conifer bark beetles, mainly by producing beetle semio-chemicals, exhausting tree defences, providing nutrition and promoting environmental adaptation (Raffa et al. 2015). *Grosmannia penicillata* and *Leptographium europhioides* were found to synthesise the beetle aggregation pheromone 2-methyl-3-buten-2-ol and similar functions have been demonstrated in a variety of ophiostomatoid fungi, indicating their ability to regulate beetle mass attacks (Zhao et al. 2015; Kandasamy et al. 2019, 2023). In contrast, *Endoconidiophora polonica* can skilfully degrade the phenolic defence compounds of spruce as a carbon source (Wadke et al. 2016), indirectly providing nutrients for its vector,

I. typographus. Fungal associates of *D. ponderosae*, *Leptographium clavigerum*, have been shown to contribute to host mortality by triggering the pine tree myriad defence responses (Fortier et al. 2024). Interestingly, the expression of high-altitude adaption-related genes in *Ips nitidus* was upregulated after feeding on *Ophiostoma bicolor*, suggesting that fungal symbionts may promote the adaptation of insect vectors to extreme environments (Wang et al. 2023).

The genus *Polygraphus* is a secondary pest; however, in recent years, it has been reported to cause an increase in tree mortality in Eurasian coniferous forests (Yin et al. 1984; Viklund et al. 2019). This genus is widely distributed in China and mainly attacks conifers, with a few species using hardwoods as a host (Yin et al. 1984). Only a few fungal associates of *Polygraphus* have been reported, most of which have been isolated from mites associated with beetles. Yin et al. (2016, 2019, 2020) successively reported seven ophiostomatalean species associated with *Polygraphus poligraphus*, three of which were subsequently isolated from beetle mite associates by Chang et al. (2020). In addition, 11 ophiostomatalean species have been isolated from mites associated with *Polygraphus aterrimus*, *P. poligraphus*, *Polygraphus szemaoensis*, *Polygraphus verrucifrons* and *Polygraphus* sp. in Yunnan and Qinghai Provinces (Chang et al. 2017, 2020). Overall, only 18 species from six genera (*Graphilbum*, *Grosmannia*, *Leptographium*, *Masuyamyces*, *Ophiostoma* and *Sporothrix*) associated with five *Polygraphus* beetles were recorded in the two Provinces (Table 1). Although 16 species of this genus have been recorded (Yin et al. 1984; Huang and Lu 2015), most of their fungal associates remain unknown.

[1] *represents the references on fungal isolation from mites associated with *Polygraphus* beetles.

In the present study, a survey of fungi associated with *P. poligraphus* and *Polygraphus rudis* was conducted on the Qinghai-Tibet Plateau between 2019 and 2020. We sought to increase our understanding of the fungal assemblages associated with *Polygraphus* beetles, based on the accurate identification and comparison of fungal associates across geographic ranges, hosts and beetle vectors.

Materials and methods

Sample collection and isolation

Adult beetles of *P. poligraphus* and *P. rudis* and/or their galleries were collected during the emergence period from four sites on the north-eastern and southern Qinghai-Tibet Plateau from 2019 to 2020 (Suppl. material 1: table S1). The branches or trunks of the host tree damaged by the beetles were cut into one-metre-long logs and brought back to the laboratory. After peeling the bark, 15 vigorous adults and/or their fresh galleries were selected for fungal isolation from each *Polygraphus* species at each sampling site. Each adult was separated into approximately 15 tissue pieces and transferred to the surface of 2% water agar. The galleries were surface-disinfected with 1.5% sodium hypochlorite and then placed on the surface of 2% water agar. After incubation in the dark at 25 °C, single hyphal tips were transferred to the surface of 2% malt extract agar (MEA) medium to purify the fungal isolates. All strains were deposited in the culture collection at the Forest Pathology Laboratory of the Chinese Academy of Forestry (CXY). Representative strains were deposited at the China Forestry Culture Collection Center, Beijing, China (CFCC).

Morphological studies

The morphological structure of each pure culture was carefully observed using an Olympus BX43 microscope (Olympus Corporation, Tokyo, Japan) and recorded using a BioHD-A20c colour digital camera (FluoCa Scientific, China, Shanghai). For the holotype of the new species, we measured the lengths and widths of 30 reproductive structures and presented the following format: (minimum–) mean minus standard deviation–mean plus standard deviation (–maximum). 5-mm diameter agar plugs were transferred from the actively growing margin of fungal colonies and placed in the centre of a 90-mm-diameter Petri plate containing 2% MEA to conduct cultural character studies. Five replicates of culture were incubated at temperatures ranging from 5 °C to 40 °C at 5 °C intervals in darkness. The colony diameters were measured daily until the mycelia reached the margins of the Petri dishes. Culture features were observed and recorded daily until the colonies no longer showed any significant changes. All the data from the type specimens were deposited in MycoBank (www.MycoBank.org).

DNA extraction, PCR amplification and sequencing

Actively growing mycelia of each representative strain were collected for DNA extraction using an Invisorb Spin Plant Mini Kit (Tiangen, Beijing, China), following the manufacturer's instructions. The internal transcribed spacer regions 1 and 2 of the nuclear ribosomal DNA operon, including the 5.8S region (ITS), internal transcribed spacer 2, part of the 28S of the rDNA operon (ITS2-LSU), β-tubulin gene

region (*tub2*) and transcription elongation factor 1-α gene region (*tef1-α*) were amplified using the primer pairs of ITS1-F/ITS4 (White et al. 1990; Gardes and Bruns 1993), ITS3/LR3 (Vilgalys and Hester 1990; White et al. 1990), Bt2a/Bt2b (Glass and Donaldson 1995) or T10/Bt2b (O'Donnell and Cigelnik 1997) or EF1F/EF2R (Jacobs et al. 2004), respectively, using 2 × Taq PCR MasterMix (Tiangen, Beijing, China), following the manufacturer's instructions. PCR and sequencing were performed according to protocols described by Wang et al. (2020, 2021).

Phylogenetic analysis

Newly-obtained sequences were identified using a standard nucleotide BLAST search in NCBI and deposited in GenBank. Reference sequences in the phylogenetic analyses were confirmed, based on the BLAST results, relevant literature and sequences downloaded from GenBank. MAFFT v.7 (Katoh et al. 2019) was used to construct the multiple sequence alignment. Molecular Evolutionary Genetic Analyses (MEGA) 7.0 (Kumar et al. 2016) were used to edit and/or splice alignments to generate combined gene datasets.

Maximum Likelihood (ML) analyses were conducted using RAxML-HPC v.8.2.3 (Stamatakis 2014) with 1000 replicates using the GTRGAMMA model. The bootstrap support values of the nodes were estimated using 1,000 bootstrap replicates after retaining the best tree. jModelTest v.2.1.7 (Darriba et al. 2012) was used to determine the best substitution models for conducting Bayesian Inference (BI) analyses in MrBayes v. 3.1.2 (Ronquist and Huelsenbeck 2003). Four Markov Chain Monte Carlo (MCMC) chains were run simultaneously from a random starting tree for 10,000,000 generations. The trees were sampled every 100 generations. Posterior probabilities were calculated, based on the remaining trees after discarding the first 25% of the sampled trees. Phylogenetic trees were edited and polished using FigTree v.1.4.3 (http://tree.bio.ed.ac.uk/software/figtree/) and Adobe Illustrator CS6. The final sequence datasets were submitted to TreeBASE (31618).

Results

Sampling collection and fungal isolation

In the present study, 442 ophiostomatalean strains were isolated from 75 vigorous adult *Polygraphus* species and 180 fresh galleries of *Picea crassifolia* and *Pinus griffithii*. Morphological characterisations and *tub2* or ITS sequence features, based on standard nucleotide BLAST searches at GenBank, were used for preliminary identification. Subsequently, 49 representative strains were selected for detailed morphological and phylogenetic analyses (Table 2).

Phylogenetic analysis

Grosmannia spp. and *Leptographium* spp.

The ITS2-LSU dataset was used to construct phylogenetic inferences for the two genera. The dataset contained 610 characters, including gaps and the best evolutionary model for BI analysis was estimated to be GTR+I+G.

Table 2. Representative strains of ophiostomatalean fungi isolated from *Polygraphus* bark beetles in this study. [1] CFCC: the China Forestry Culture Collection Center; CXY: the culture collection at the Forest Pathology Laboratory of the Chinese Academy of Forestry.

The results showed that our eight representative isolates nested into three complexes, namely the *G. penicillata*, *L. lundbergii* and *L. olivaceum* complexes (Fig. 1). Amongst these, the *G. penicillata* complex belongs to *Grosmannia*, whereas the *L. lundbergii* and *L. olivaceum* complexes belong to *Leptographium*. Subsequently, we constructed the phylogenetic inference of *tub2*, *tef1-α* and the concatenated (*tub2*+*tef1-α*) datasets for each complex.

Grosmannia penicillata complex

The *tub2*, *tef1-α* and concatenated (*tub2*+*tef1-α*) datasets were aligned (containing 402, 694 and 1096 characters, including gaps, respectively) and used to construct the phylogenetic inference. The best models of the three datasets for BI analysis were estimated as HKY+I (*tub2* dataset) and GTR+G (*tef1-α* and concatenated datasets). Based on the concatenated tree (Fig. 2), the seven isolates formed three separate well-supported terminal clades, representing two known and one undescribed taxa: *G. crassifolia* (Taxon 1), *G. maixiuensis* (Taxon 2) and *Grosmannia* sp. 1 (Taxon 3). These three species formed a subclade with *G. chlamydata* and *G. nitidi* that was phylogenically consistent, based on the three datasets (Fig. 2, Suppl. material 2: figs S1, S2).

Leptographium lundbergii complex

The *tub2*, *tef1-α* and concatenated (*tub2*+*tef1-α*) datasets were aligned (containing 373, 666 and 1039 characters, including gaps, respectively) and used to construct the phylogenetic inference. The best models of the three datasets for BI analysis were SYM+I, HKY+G and GTR+G. Based on the concatenated tree (Fig. 3), our ten isolates formed four separate well-supported terminal clades, representing three known (Taxon 4: *L. griffithii*; Taxon 5: *L. jilongense*; Taxon 7: *L. yadongense*) and one undescribed (Taxon 6) taxa. Taxa 4, 5 and 6 were sister species and formed a subclade with *L. panxianense*, *L. yunnanensis*, *L. puerense*, *L. wushanense* and *L. conjunctum*, all of which were isolated from *Pinus* trees in southwest China (Fig. 3, Suppl. material 2: figs S3, S4). The four isolated strains were identical in sequence to the two strains isolated from *Ips schmutzenhoferi*, representing *L. yadongense*, which was a phylogenetic sister to *L. sejilanum* (Fig. 3, Suppl. material 2: figs S3, S4).

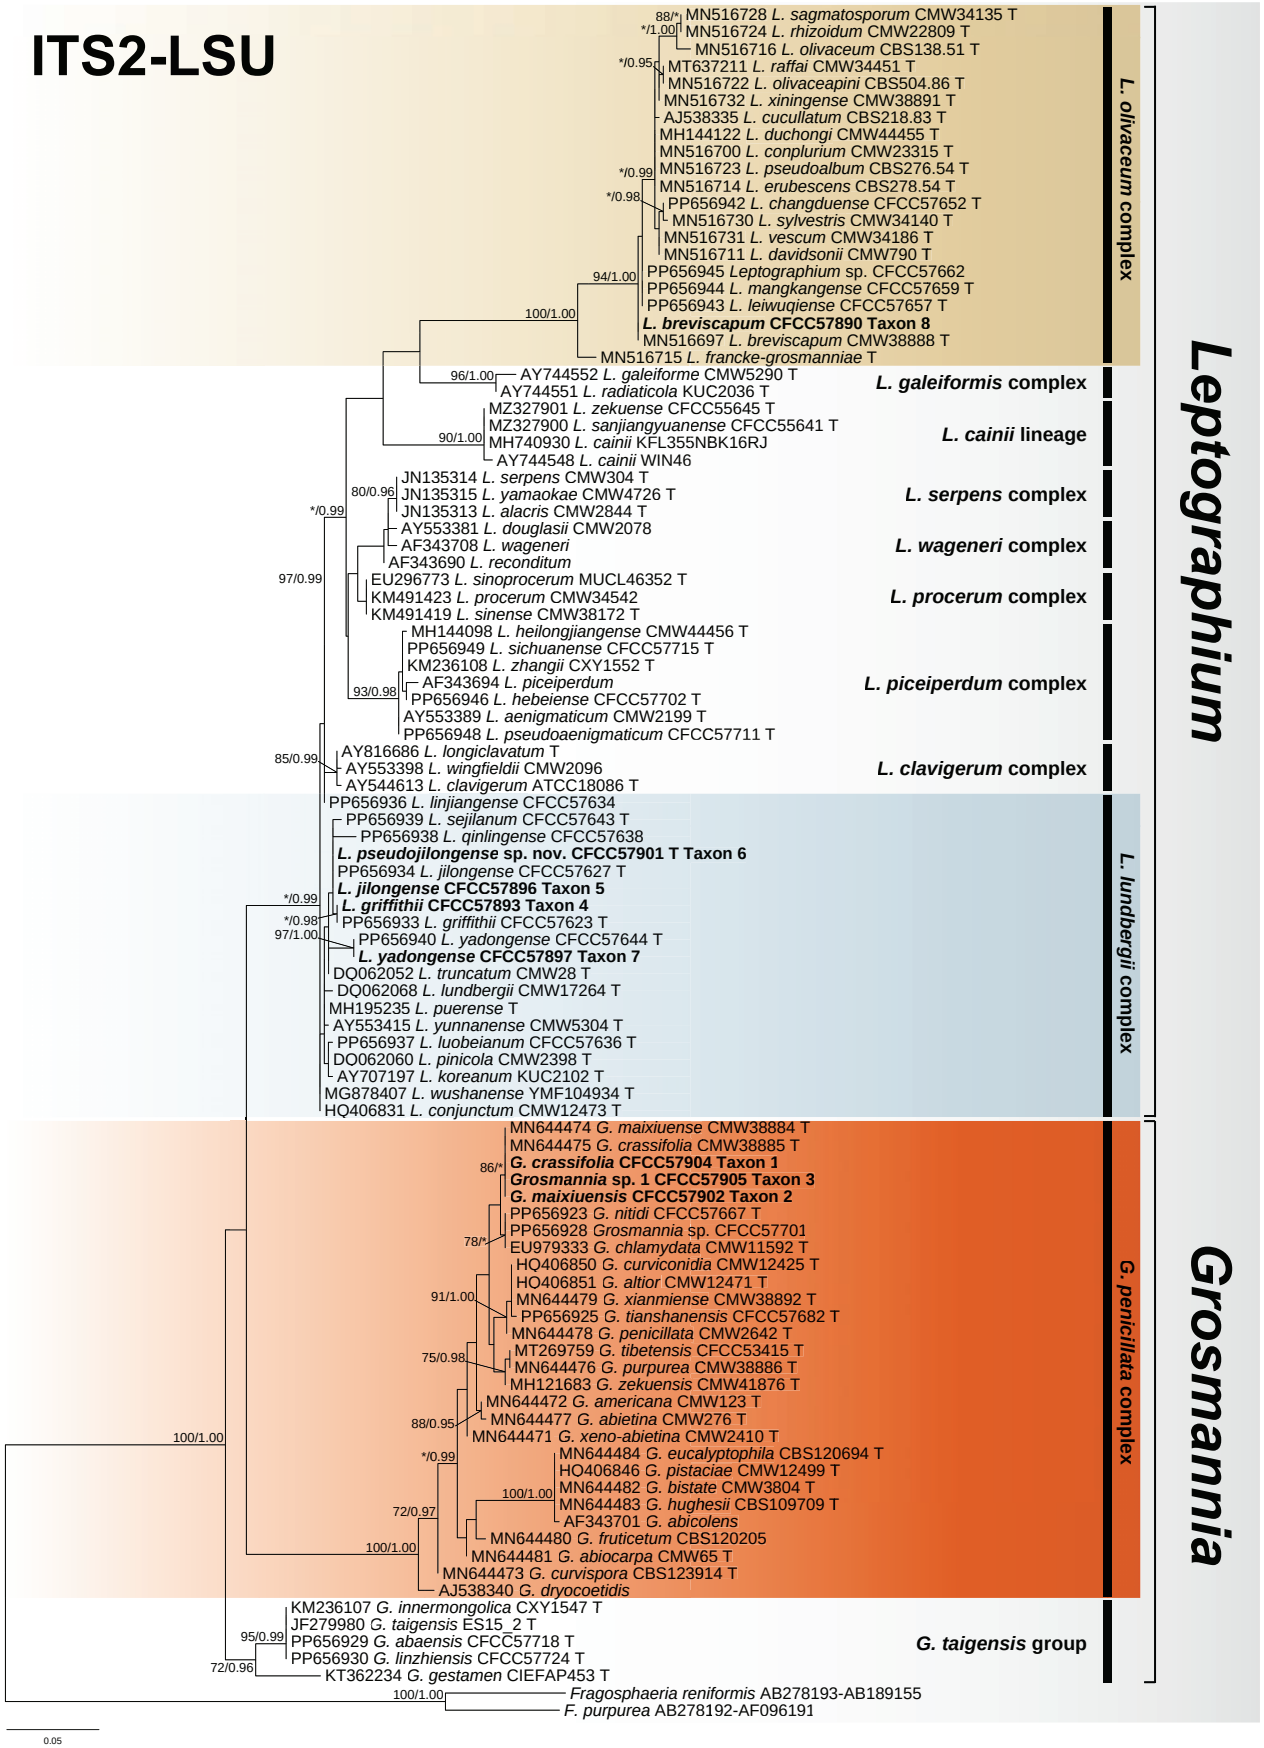

Figure 1. Phylogram of *Grosmannia* spp. and *Leptographium* spp. based on ITS2-LSU sequence data. The ML bootstrap support values ≥ 70% and posterior probability values ≥ 0.9 are recorded at the nodes. T = ex-type isolates.

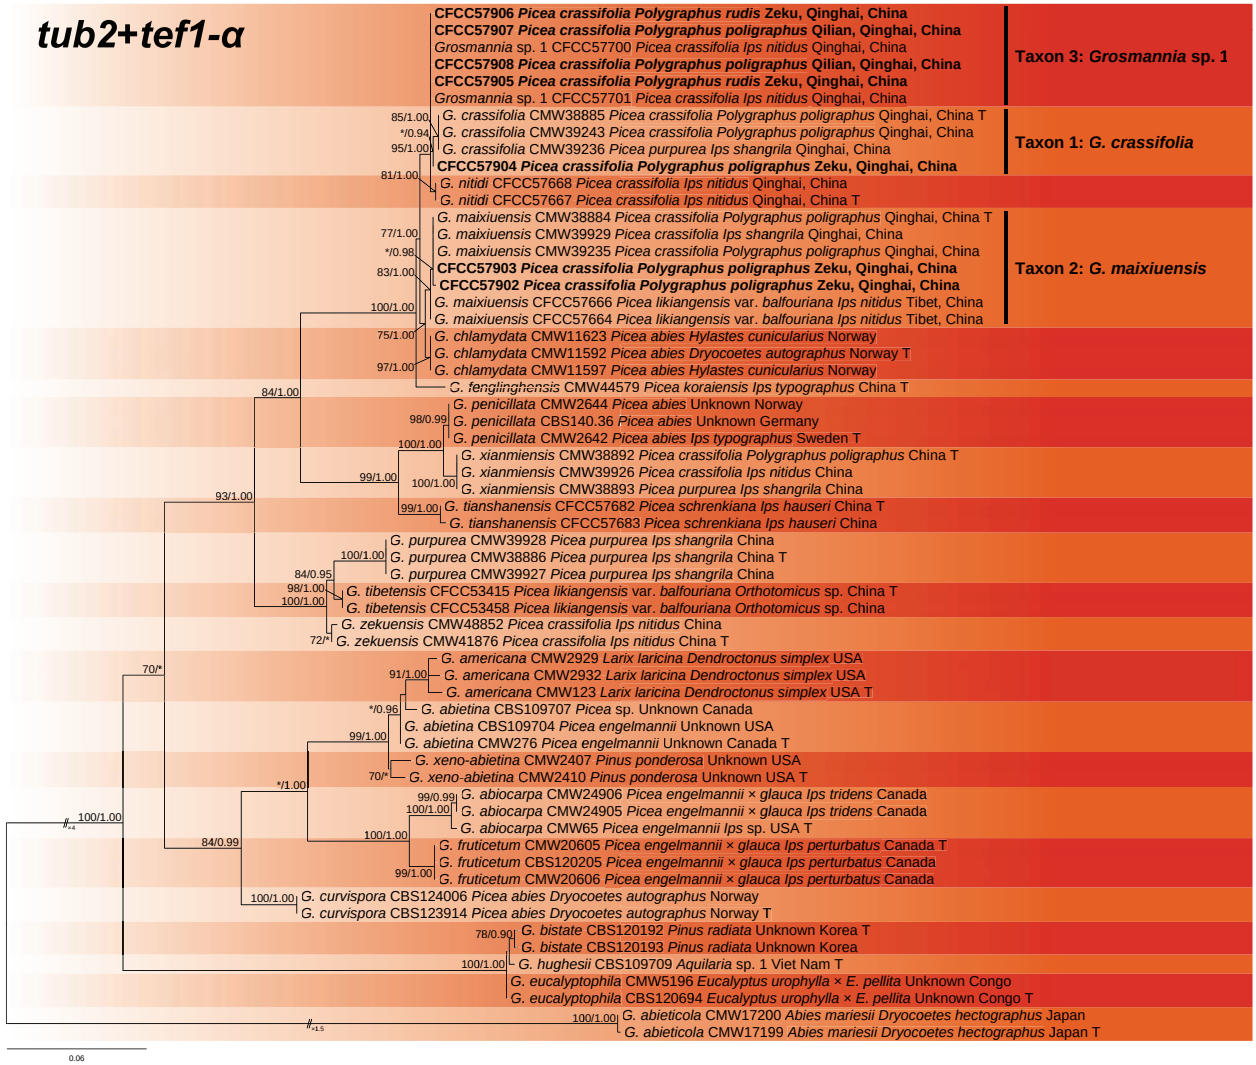

Figure 2. Phylogram of *Grosmannia penicillata* complex (including Taxa 1–3) based on combined (*tub2*+*tef1-α*) sequence data. The ML bootstrap support values ≥ 70% and posterior probability values ≥ 0.9 are recorded at the nodes. T = ex-type isolates.

Leptographium olivaceum complex

The *tub2*, *tef1-α* and concatenated (*tub2*+*tef1-α*) datasets were aligned (containing 278, 677 and 955 characters, including gaps, respectively) and used to construct the phylogenetic inference. The best models of the three datasets for BI analysis were estimated as (*tub2* dataset) and GTR+G (*tef1-α* and concatenated datasets). Based on the concatenated tree (Fig. 4), the three isolates formed a separate, well-supported, terminal clade representing *L. breviscapum* (Taxon 8). The 10 strains of *L. breviscapum* formed a subclade with *L. leiwuqiense*, *L. mangkangense* and *Leptographium* sp. 1, all of which were isolated from *Picea* trees on the Qinghai-Tibet Plateau (Fig. 4, Suppl. material 2: figs S5, S6).

Ophiostoma spp.

An ITS dataset was used to construct a phylogenetic inference for this genus. The dataset contained 743 characters, including gaps and the best evolutionary model for BI analysis was estimated to be GTR+I+G. The results showed

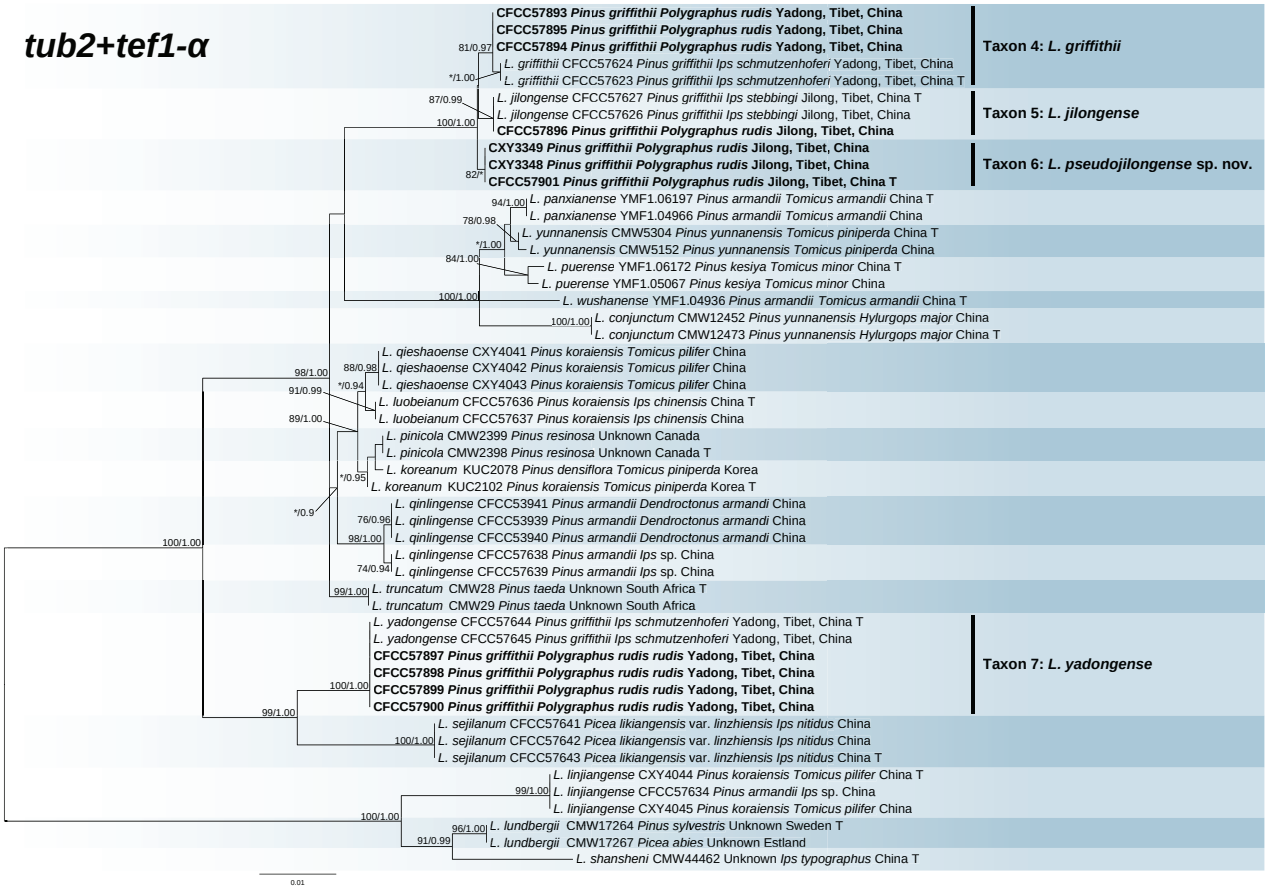

Figure 3. Phylogram of *Leptographium lundbergii* complex (including Taxa 4–7) based on combined (*tub2+tef1-α*) sequence data. The ML bootstrap support values ≥ 70% and posterior probability values ≥ 0.9 are recorded at the nodes. T = ex-type isolates.

that our eight representative isolates nested into two complexes and one Group A, namely the *O. clavatum* complex, *O. ips* complex and Group A (Fig. 5). Subsequently, we constructed the phylogenetic inference of *tub2*, *tef1-α* and/or the concatenated (*tub2+tef1-α* or ITS+*tub2*) datasets for each complex or Group.

Ophiostoma clavatum complex

The *tub2*, *tef1-α* and concatenated (*tub2+tef1-α*) datasets were aligned (containing 438, 594 and 1032 characters, including gaps, respectively) and used to construct the phylogenetic inference. The best models of the three datasets for BI analysis were estimated as HKY+I, GTR+G and GTR+I+G. Based on the concatenated tree (Fig. 6), our ten isolates formed three separate well-supported terminal clades, representing two known (Taxon 9: *O. pseudobrevipilosi*; Taxon 10: *O. stebbingi*) and one undescribed (Taxon 11: *Ophiostoma* sp. 1) taxa. *Ophiostoma pseudobrevipilosi*, *O. stebbingi* and *Ophiostoma* sp. 1 formed the main subclade in this complex with *O. ainoae*, *O. brevipilosi*, *O. pseudobrevipilosi*, *O. schmutzenhoferi*, *O. shangrilae* and *O. yadongense* (Fig. 6, Suppl. material 2: figs S7, S8).

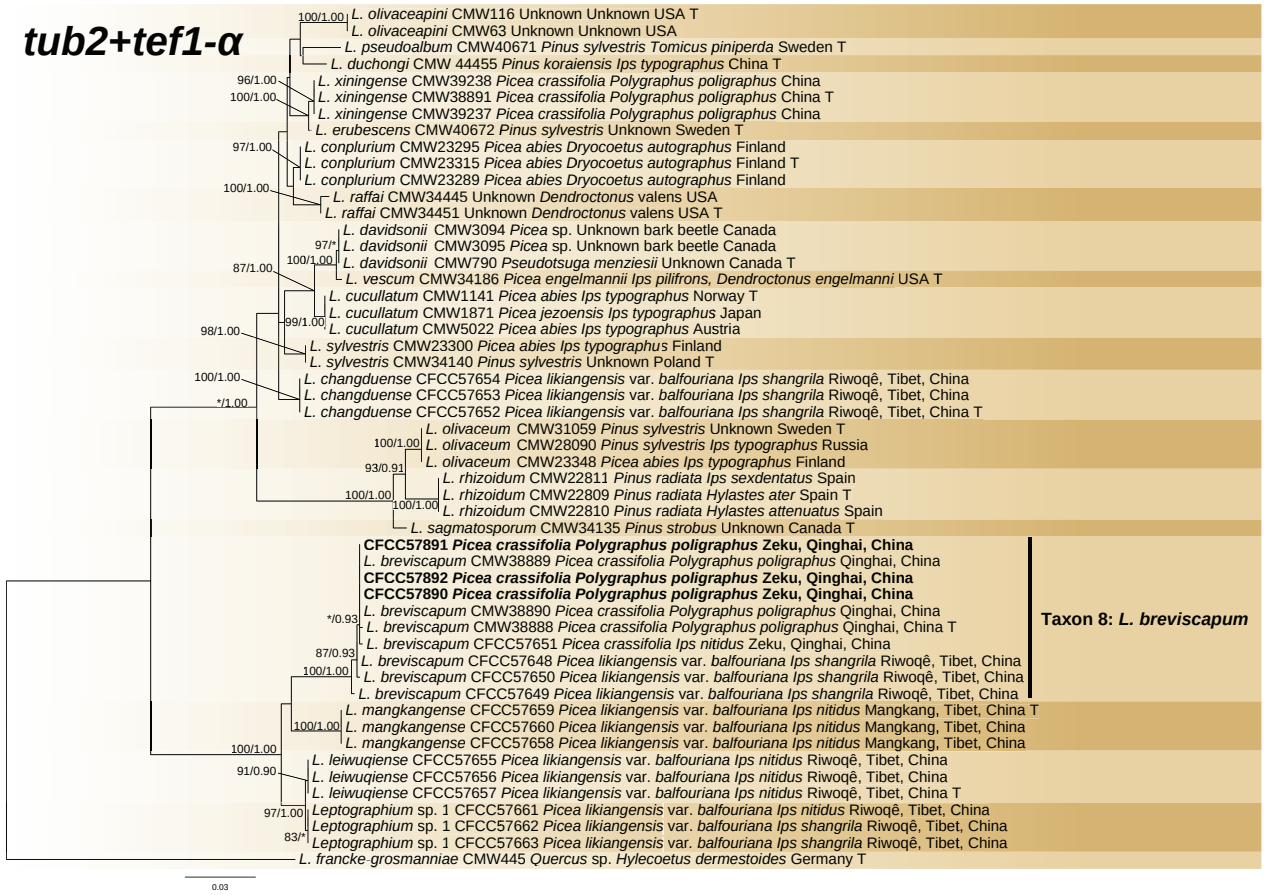

Figure 4. Phylogram of *Leptographium olivaceum* complex (including Taxon 8) based on combined (*tub2*+*tef1-α*) sequence data. The ML bootstrap support values ≥ 70% and posterior probability values ≥ 0.9 are recorded at the nodes. T = ex-type isolates.

Ophiostoma ips complex

The *tub2* dataset was aligned (containing 274 characters including gaps) and used to construct a phylogenetic inference. The best model of the three datasets for BI analysis was estimated to be HKY+I. The seven isolates formed two clades: *O. bicolor* (Taxon12) and *O. shigatsense* (Taxon 13) (Fig. 7).

Group A

The ITS, *tub2* and concatenated (ITS+*tub2*) datasets were aligned (containing 685, 445 and 1130 characters, including gaps) and used to construct the phylogenetic inference. The best models of the three datasets for BI analysis were estimated to be GTR+I+G (ITS dataset) and GTR+G (ITS and concatenated datasets). Based on the concatenated tree (Fig. 8), the 11 isolates formed three separate well-supported terminal clades representing three known taxa (Taxon 14: *O. maixiuense*, Taxon 15: *O. pacis* and Taxon 16: *O. sanum*). *Ophiostoma maixiuense* and *O. sanum* showed intraspecific sequence variation and were phylogenetic sisters to *O. aggregatum* and *O. pacis* (Fig. 8, Suppl. material 2: figs S9, S10).

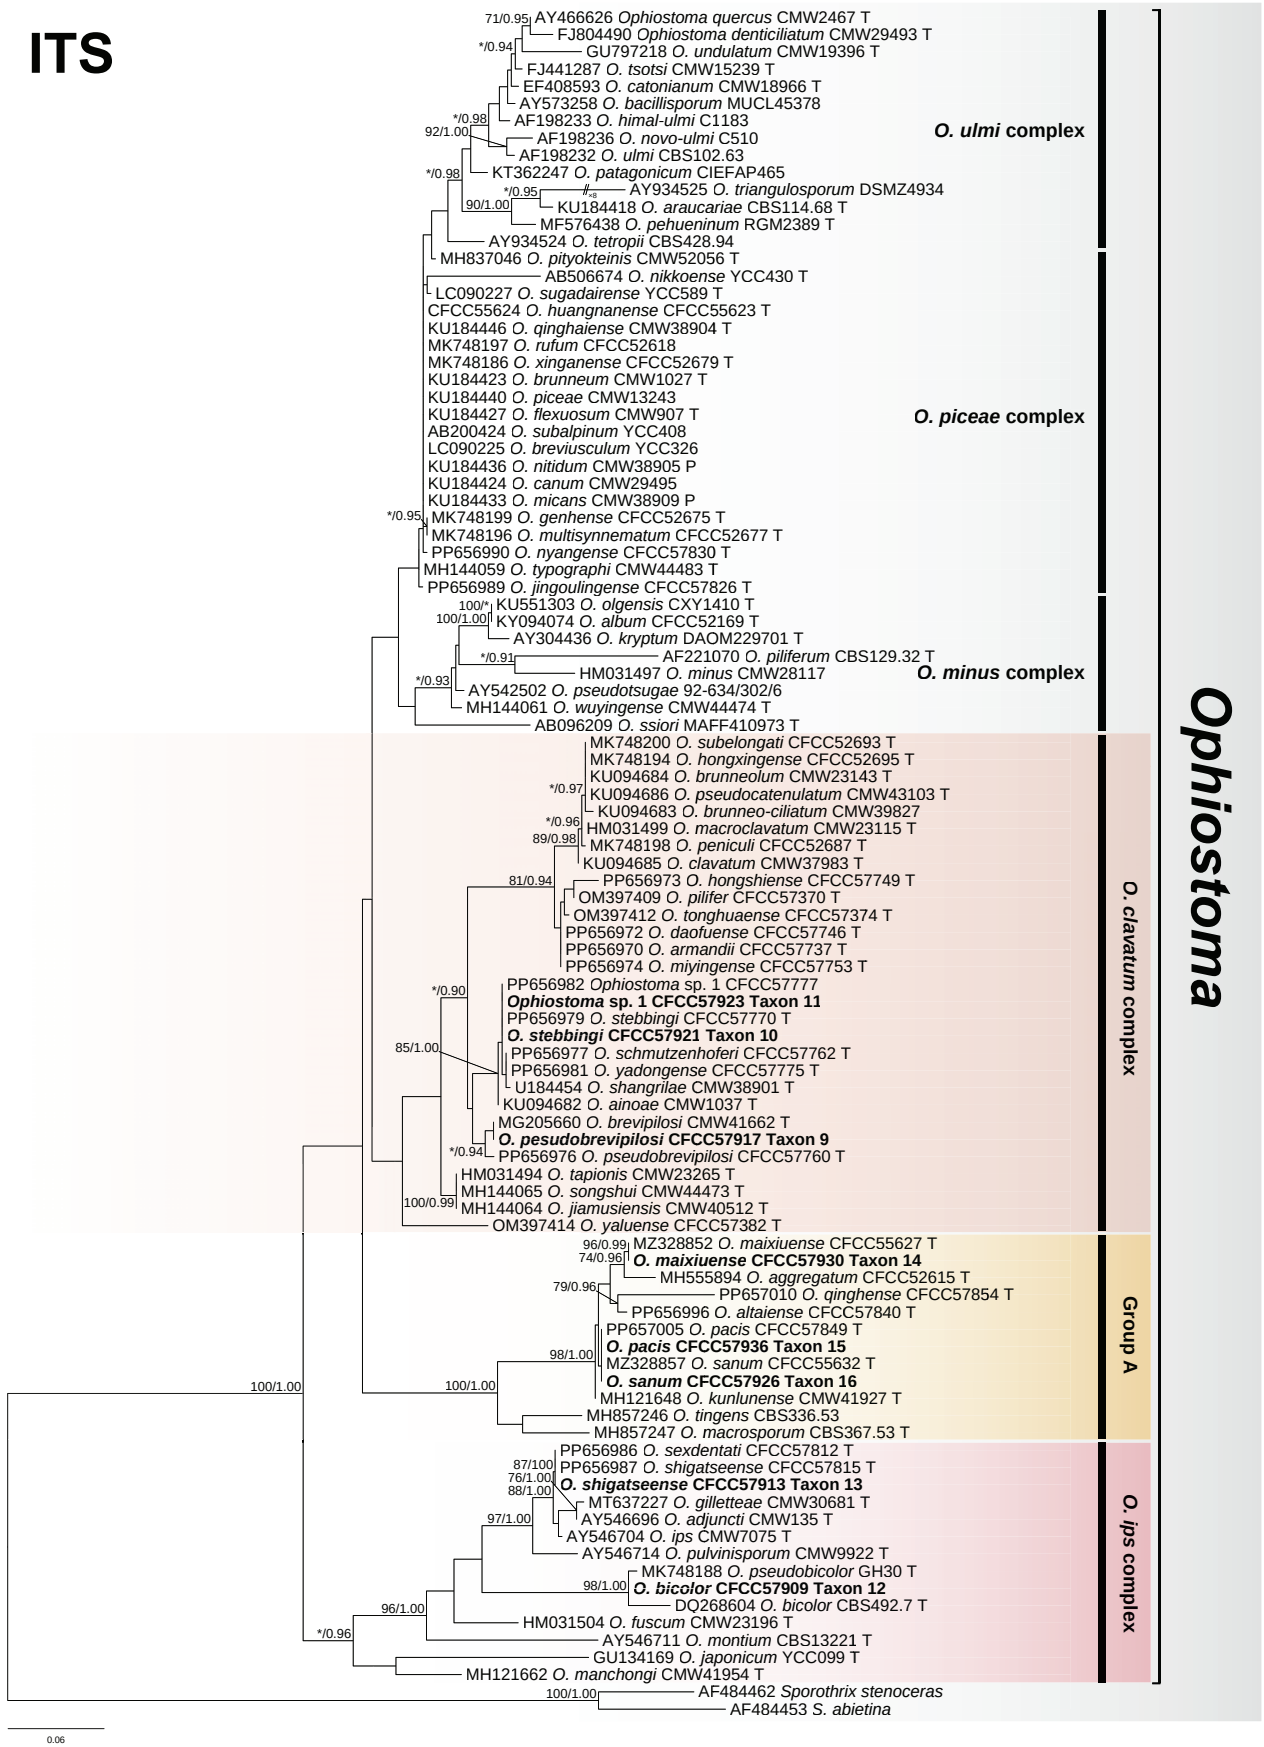

Figure 5. Phylogram of *Ophiostoma* spp. based on ITS sequence data. The ML bootstrap support values ≥ 70% and posterior probability values ≥ 0.9 are recorded at the nodes. T = ex-type isolates.

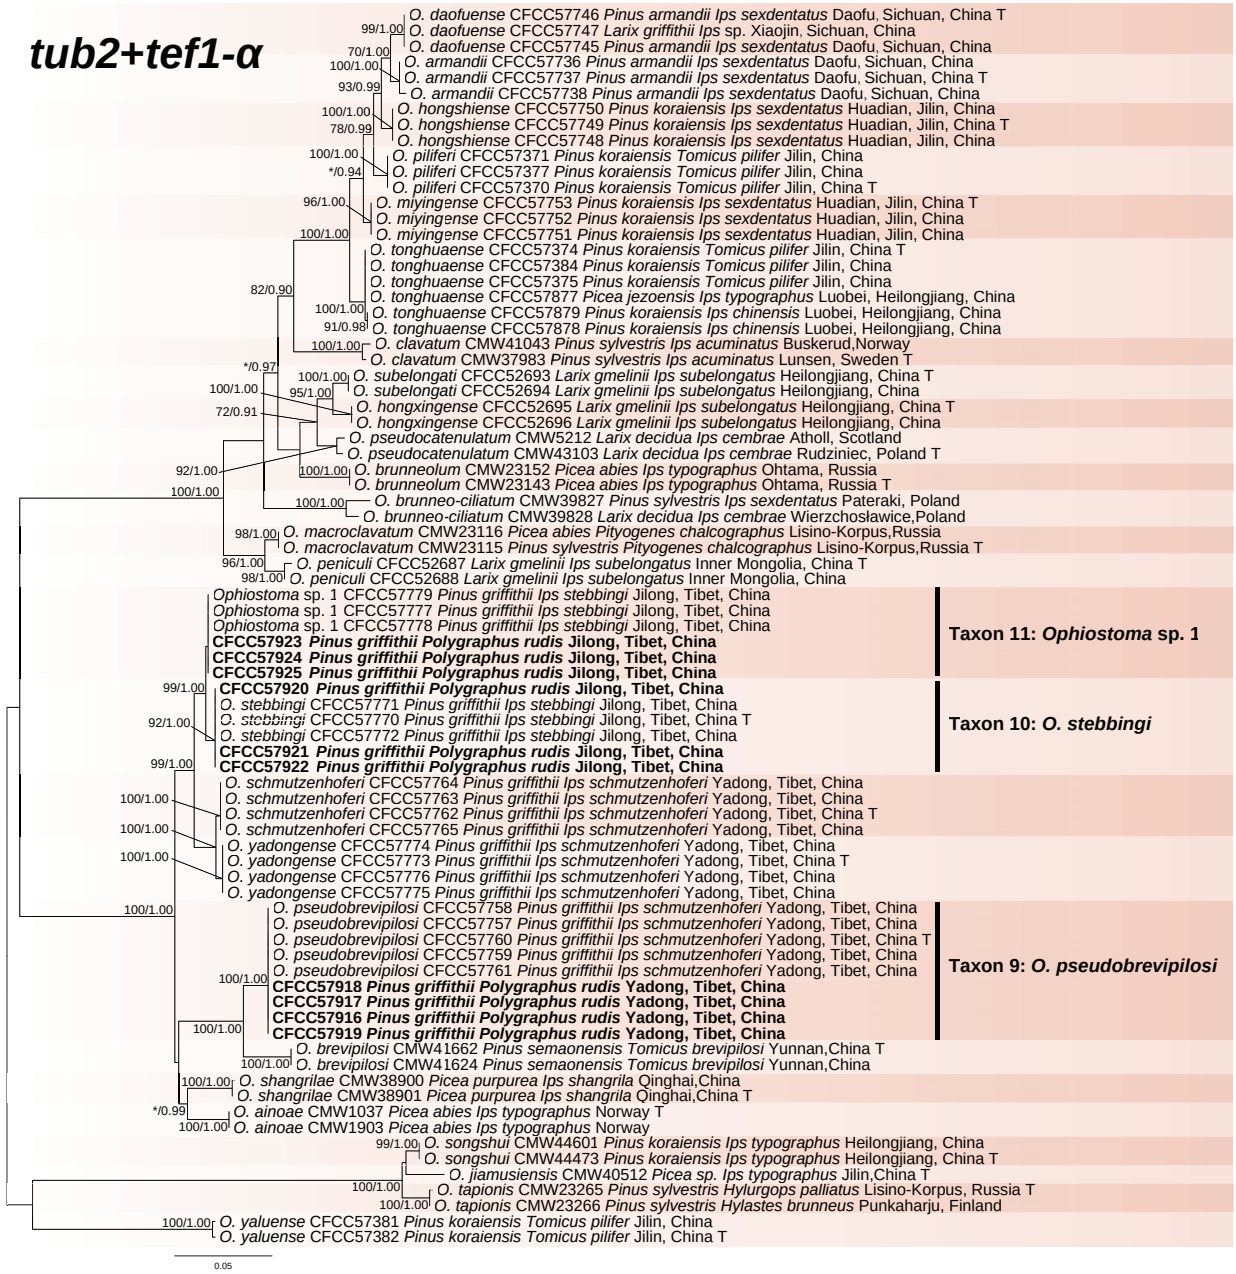

Figure 6. Phylogram of *Ophiostoma clavatum* complex (including Taxa 9–11) based on combined (*tub2*+*tef1-α*) sequence data. The ML bootstrap support values ≥ 70% and posterior probability values ≥ 0.9 are recorded at the nodes. T = ex-type isolates.

Taxonomy

***Leptographium pseudojilongense* Z. Wang & Q. Lu, sp. nov.**
MycoBank No: 855413
Taxon 6, Fig. 9

Etymology. The epithet *pseudojilongense* (Latin) refers to its sister species *L. jilongense*.

Holotype. CXY3312.

Description. Sexual morph: not observed. **Asexual morph:** ***Leptographium***-like. ***Conidiophores*** occurring singly, upright, arising directly from the mycelium,

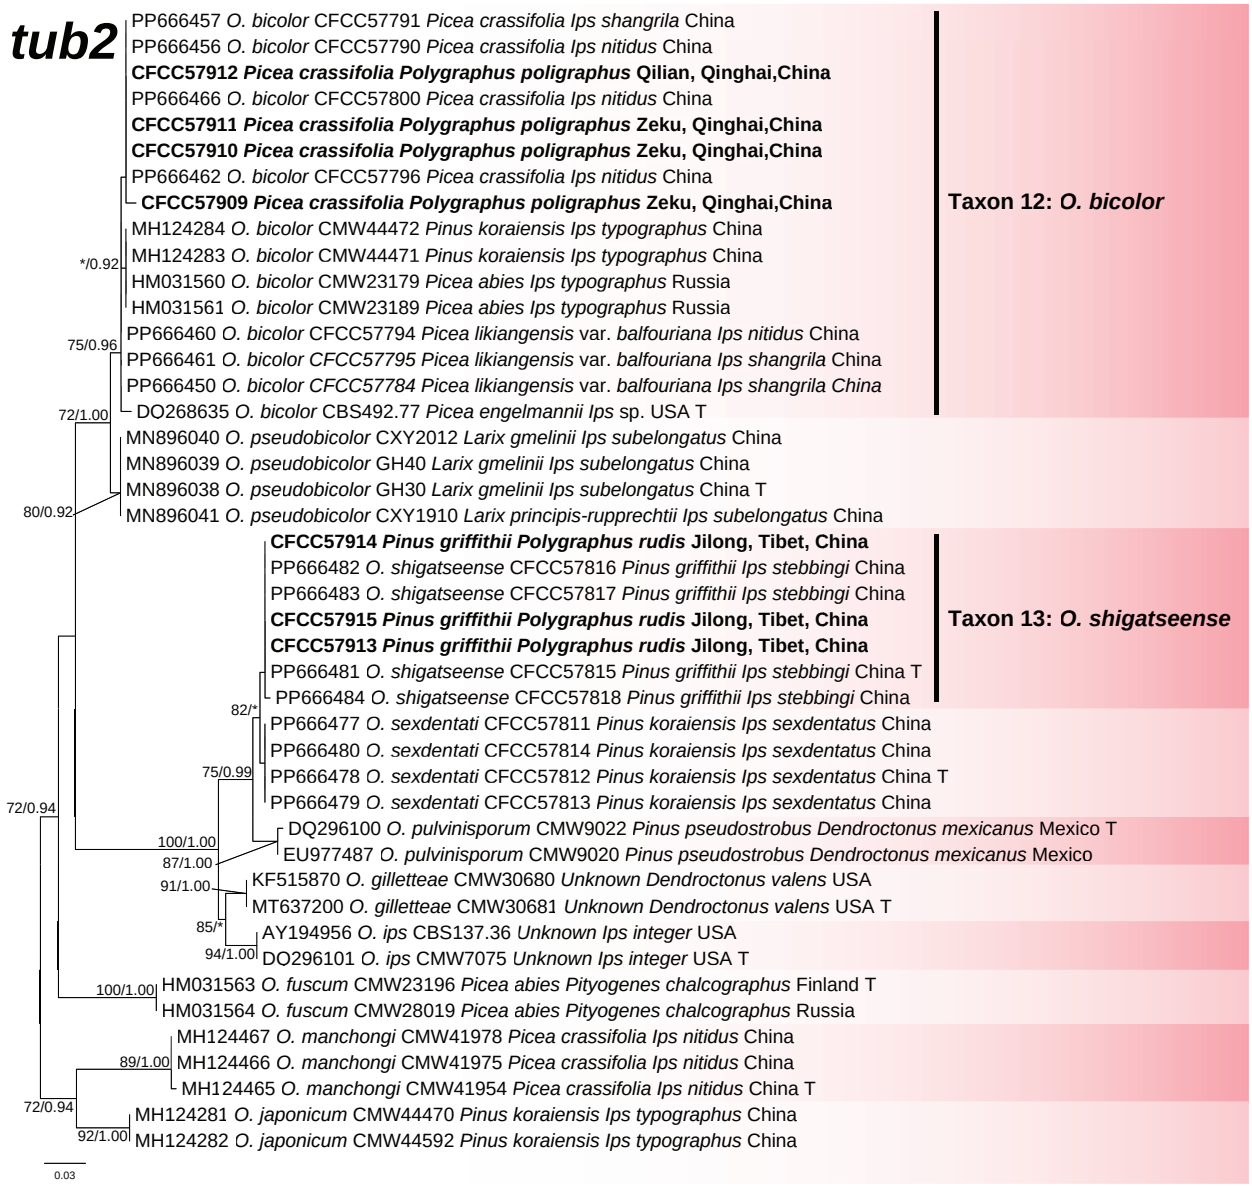

Figure 7. Phylogram of *Ophiostoma ips* complex (including Taxa 12–13) based on *tub2* sequence data. The ML bootstrap support values ≥ 70% and posterior probability values ≥ 0.9 are recorded at the nodes. T = ex-type isolates.

macronematous, mononematous, (247.7–)343.3–484.6(–513.7) µm in length including the conidiogenous apparatus, rhizoid-like structures absent. ***Stipes*** light olivaceous, not constricted, cylindrical, simple, 3–10-septate, (98.8–)103.0–230.0(–301.2) µm in length, (9.0–)11.1–16.9(–18.6) µm wide at base, the basal cell swollen or not, (7.1–)8.5–14.2(–16.6) µm wide below primary branches, apical cell not swollen. ***Conidiogenous apparatus*** (100.8–)180.1–362.1(–417.4) µm in length, excluding the conidial mass, consisting of 1–4 series of branches, the primary branching type B. ***Primary branches*** light olivaceous, cylindrical, (15.4–)19.6–31.8(–35.4) × (6.2–)7.3–10.6(–12.3) µm; ***secondary branches*** light olivaceous, aseptate, (12.4–)13.3–16.7(–18.4) × (6.0–)6.4–9.5(–10.2) µm; ***tertiary branches*** light olivaceous or hyaline, aseptate, (8.0–)8.4–14.0(–16.1) × 5.3–7.6(–8.9) µm. ***Conidiogenous cells*** discrete, 2–3 per branch, smooth or rough, cylindrical, (16.9–)22.2–35.4(–52.6) × (3.9–)4.0–4.8(–5.1) µm. ***Conidia*** hyaline, smooth, aseptate, obovoid, (11.9–)12.9–15.7(–17.9) × (5.5–)6.3–7.8(–8.2) µm.

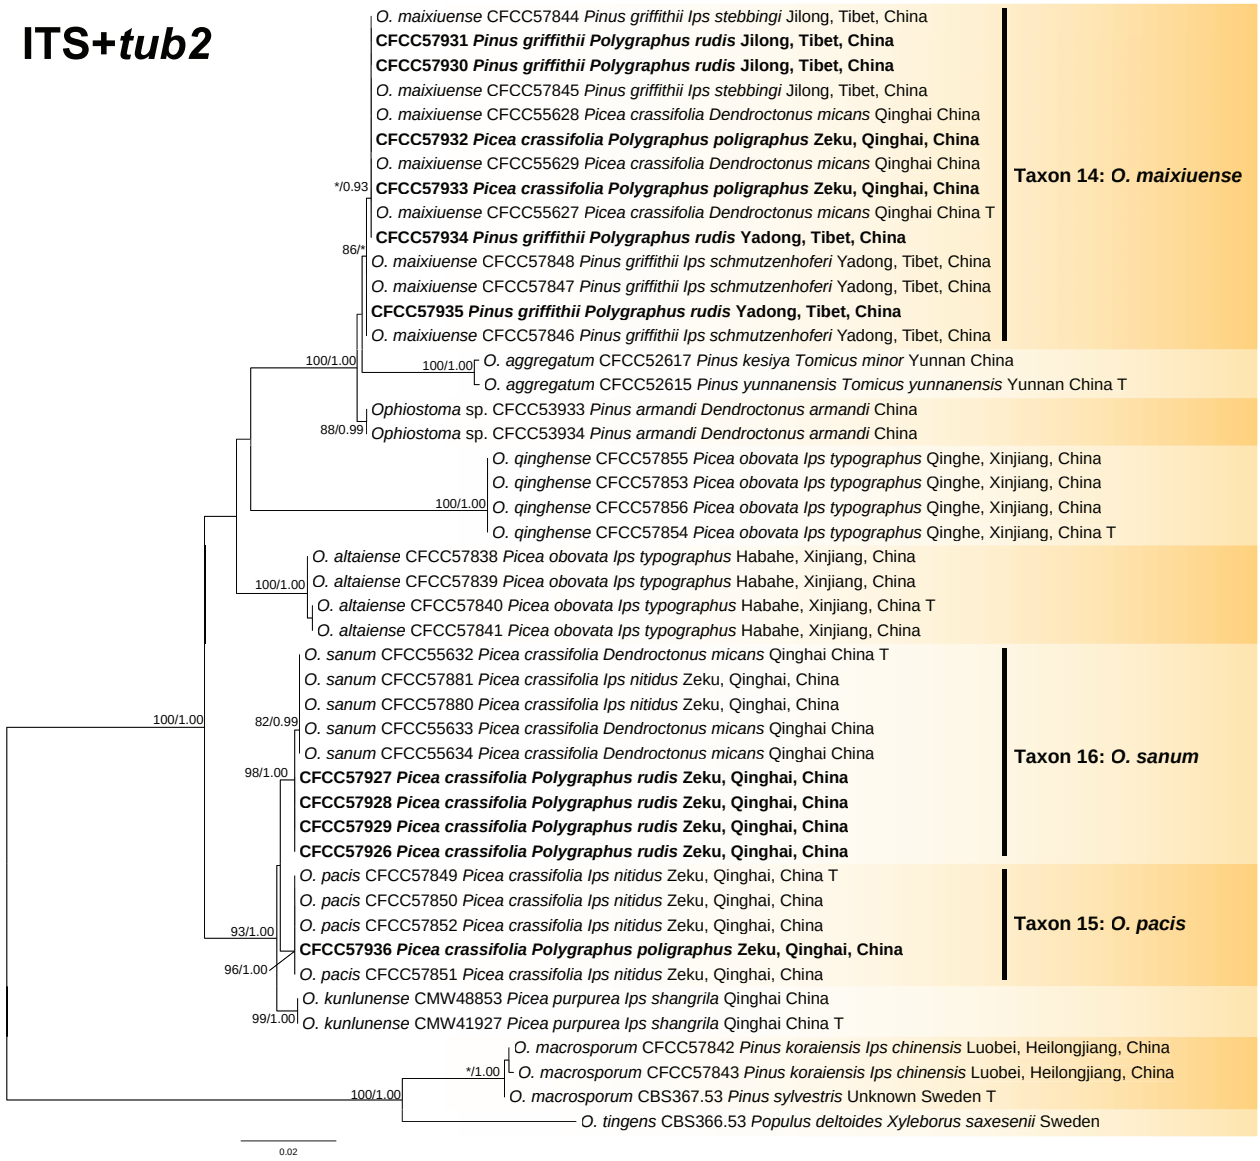

Figure 8. Phylogram of Group A (including Taxa 14–16) based on combined (ITS+*tub2*) sequence data. The ML bootstrap support values ≥ 70% and posterior probability values ≥ 0.9 are recorded at the nodes. T = ex-type isolates.

Culture characters. Colonies on 2% MEA at 25 °C reaching a diameter of 50.1 mm in 4 days, initially hyaline or light white, later becoming light olivaceous from the centre of the colony to the sides, then becoming dark olivaceous, mycelium submerged and superficial with abundant aerial mycelia and the colony margin thinning radially. Optimal temperature for growth was 25 °C, with slow growth observed at 5 °C (45.3 mm in 30 days) and no growth at 35 °C.

Associated insects. *Polygraphus rudis*.

Hosts. *Pinus griffithii*.

Material examined. China • Xizang Autonomous Region, Shigatse City, Jilong County, from *Polygraphus rudis* infesting *Pinus griffithii*, July 2019, Z. Wang and Q. Lu, holotype: CXY3312, ex-type culture CFCC57901, ibid. CXY3348, CXY3349.

Notes. *Leptographium pseudojilongense* was a phylogenetic sister to *L. griffithii* and *L. jilongense* (Fig. 9), both of which were associated with *Pinus griffithii* in Shigatse, Xizang (Wang et al. 2024). *Leptographium pseudojilongense* can be distinguished from *L. griffithii* in the concatenated alignment by 1/373 bp in *tub2*

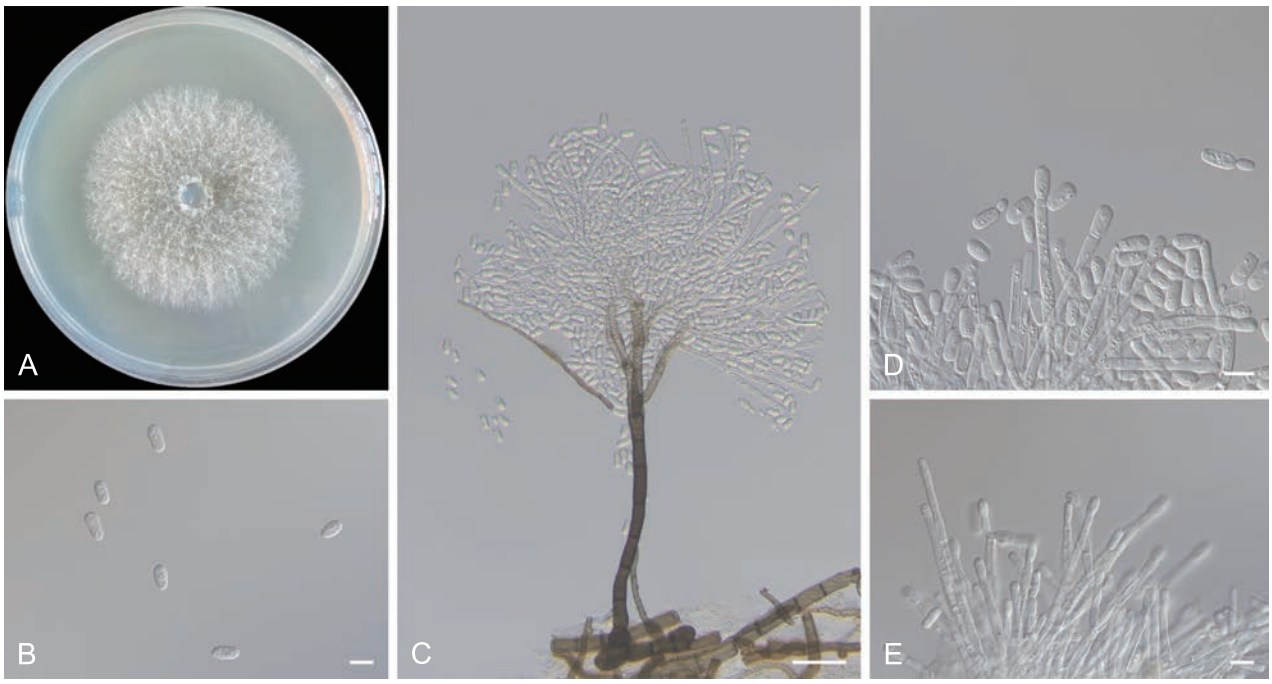

Figure 9. Morphological characteristics of *Leptographium pseudojilongense* sp. nov. (Taxon 9, CXY3312, holotype) **A** four-day-old cultures on 2% MEA **B–E** *Leptographium*-like asexual morph: conidiogenous cells and conidia. Scale bars: 10 μm (**B, D, E**); 40 μm (**C**).

and 3/666 bp in *tef1-α* and from *L. jilongense* in the concatenated alignment by 3/666 bp in *tef1-α*. In terms of morphological characteristics, *L. pseudojilongense* can be distinguished from the other two species by the presence of a *leptographium*-like asexual state, which is absent in the latter two. For culture characteristics, the optimum growth temperature for both was 25 °C, but the former grew slower than the latter two (4 days: 50.1 mm vs. 64.5 and 76.0 mm). At 5 °C, *L. pseudojilongense* was observed growing slowly with 45.3 mm in 30 days, whereas the other two did not grow. Furthermore, *L. pseudojilongense* was isolated from Jilong County, whereas *L. griffithii* and *L. jilongense* were isolated from *Ips schmutzenhoferi* from Yadong County and *Ips stebbingi* from Jilong County, respectively.

Discussion

In total, 442 ophiostomatalean strains representing 16 species were obtained from adult *Polygraphus* beetles and their galleries in *Picea crassifolia* and *Pinus griffithii* on the north-eastern and southern Qinghai-Tibet Plateau. These species were assigned to *Grosmannia* (*G. crassifolia*, *G. maixiuensis* and *Grosmannia* sp. 1 in *G. penicillata* complex), *Leptographium* (*L. griffithii*, *L. jilongense*, *L. pseudojilongense* and *L. yadongense* in *L. lundbergii* complex; *L. breviscapum* in *L. olivaceum* complex) and *Ophiostoma* (*O. pseudobrevipilosi*, *O. stebbingi* and *Ophiostoma* sp. 1 in *O. clavatum* complex; *O. bicolor* and *O. shigatsense* in *O. ips* complex; *O. maixiuense*, *O. pacis* and *O. sanum* in Group A). Amongst them, 12 species were first recorded as associated with *Polygraphus* beetles in China. Yin et al. (2016, 2019, 2020) reported seven ophiostomatalean associates of *P. poligraphus*, but we only collected three of them, which may be because of sample size and sampling time or because the remaining four species are occasional (the previous reports did not count the proportions of each species). To date, three genera (20 species) of

ophiostomatalean fungi have been reported to be associated with *Polygraphus* beetles in China (Yin et al. 2016, 2019, 2020), increasing to six genera (30 species) when the fungi isolated from mites associated with these beetles are included (Chang et al. 2017, 2020), showing an abundance of species diversity (Tables 1, 3).

The dominant species in this study were *O. maixiuense*, *O. bicolor*, *L. yadongense* and *O. pseudobrevipilosi*, representing 20.8%, 18.1%, 17.4% and 13.4% of the ophiostomatalean isolates, respectively, while the other 12 species all had < 10% (Table 3). *Ophiostoma maixiuense* was first reported to be associated with *Dendroctonus micans* infesting *P. crassifolia* on the north-eastern Qinghai-Tibet Plateau (Wang et al. 2021). This species was also obtained from *P. poligraphus* from the same host tree and sampling location. In addition, although several fungal associates of *P. rudis*, *I. schmutzenhoferi* and *I. stebbingi* have been isolated from *P. griffithii* in the Jilong and Yadong Counties on the southern Qinghai-Tibet Plateau, only *O. maixiuense* was shared (Table 3; Wang et al. (2024)). Therefore, this species may be widespread on the Qinghai-Tibet Plateau and its pathogenicity to host trees and association with bark beetles deserve further study. *Ophiostoma bicolor* is frequently associated with bark beetles that harm spruce trees, such as some *Ips* and *Polygraphus* beetles in the Northern Hemisphere (Yamaoka et al. 1997; Kirisits 2004; Alamouti et al. 2007; Chang et al. 2019, 2020; Wang et al. 2021, 2024). It plays multiple roles in the association between beetles and spruce. Solheim (1988) found that it is weakly pathogenic to spruce trees, which may induce the host defence rather than deplete it (Liu et al. 2022). This is not necessarily beneficial during the early stages of insect vector attacks on trees (Mageroy et al. 2020). Conversely, although *O. bicolor* is not attractive to *I. typographus* (Kandasamy et al. 2019; Zhao et al. 2019), *I. nitidus* prefers to feed on *O. bicolor*-colonised substrates and may benefit from their aid in detoxification and improved ecological fitness (Wang et al. 2023). The mechanisms underlying the functional diversity traits in *O. bicolor* and their roles in tree–beetle–fungal interactions need to be further explored.

Table 3. Strains of ophiostomatalean fungi associated with *Polygraphus* in this study.

Taxon	Genus	Species group and complex	Species	Numbers of isolates[1]					Total	Total Percentages
				PrJ	PrY	PrZ	PpZ	PpQ		
1	*Grosmannia*	*G. penicillata*	*G. crassifolia*				8		8	1.81%
2			*G. maixiuensis*				9		9	2.04%
3			*Grosmannia* sp. 1			10		2	12	2.71%
4	*Leptographium*	*L. lundbergii*	*L. griffithii*		14				14	3.17%
5			*L. jilongense*	1					1	0.23%
6			*L. pseudojilongense*	3					3	0.68%
7			*L. yadongense*		77				77	17.42%
8		*L. olivaceum*	*L. breviscapum*				33		33	7.47%
9	*Ophiostoma*	*O. clavatum*	*O. pseudobrevipilosi*		59				59	13.35%
10			*O. stebbingi*	16					16	3.62%

15			*O. pacis*				1		1	0.23%
16			*O. sanum*			15			15	3.39%
Total				70	189	25	96	62	442	100.00%

[1] PrJ = *Polygraphus rudis* from Jilong County; PrY = *P. rudis* from Yadong County; PrZ = *P. rudis* from Zeku County; PpZ = *P. poligraphus* from Zeku County; PpQ = *P. poligraphus* from Qilian County.

Comparisons of the fungal assemblages of bark beetles from the north-eastern and southern Qinghai-Tibet Plateau showed different patterns (30 vs. 12 fungal species), with only *O. maixiuense* being a shared species (Suppl. material 1: tables S2, S3), which may be due to biogeographic barriers and host species. On the north-eastern Qinghai-Tibet Plateau, there are 14, 21 and 14 fungal associates of *Dendroctonus*, *Ips* and *Polygraphus*, respectively (Yin et al. 2016, 2019, 2020; Chang et al. 2020; Wang et al. 2021, 2024). *Ophiostoma ainoae*, *O. bicolor*, *O. nitidum*, *O. sanum* and *O. shangrilae* are shared by these three beetle genera, the latter three of which are currently found only on the Qinghai-Tibet Plateau, whereas the first two are thought to be widely distributed in the coniferous forests of China and are associated with a variety of bark beetles (Chang et al. 2019; Wang et al. 2024). Six fungal associates of *Polygraphus* were shared only with *Ips* and only two were shared with *Dendroctonus* (Suppl. material 1: table S2). This may be because of overlap in the niches of the first two genera of beetles. Furthermore, *Dendroctonus* mainly harms trunks below the DBH (diameter at breast height) of the host tree, which is not the preferred choice for *Polygraphus* and *Ips*. On the southern Qinghai-Tibet Plateau, although the straight-line distance between Jilong and Yadong Counties is not large, the fungal assemblages of bark beetles from the two Counties are divergent, with only one of the 12 species shared (Suppl. material 1: table S3). Interestingly, the fungal associations of different beetles at the two sites were highly coincident. Four of the six fungal associates of *P. rudis* are shared with *I. stebbingi*. Similarly, all four of the *P. rudis*' fungal associates in Yadong County were also isolated from *I. schmutzenhoferi* by Wang et al. (2024). This suggests that the biogeographic barrier caused by the high mountain-and-gorge landform on the southern slopes of the Himalayas creates this fungal assemblage pattern of bark beetles, even though the host species are the same and geographical distances are not far.

Overall, this study deepens our understanding of the composition of ophiostomatoid fungi associated with bark beetles, especially *Polygraphus*, on the Qinghai-Tibet Plateau. The discovery of a large number of new fungal species and new tree-bark beetle-fungal associations has made it an urgent task to reveal their biological functions and ecological features.

Abstract

Calonectria leaf blight caused by *Calonectria* species is one of the most important diseases associated with *Eucalyptus* plantations in Asia and South America. This study aimed to clarify the distribution patterns of *Calonectria* species residing in different species complexes associated with diseased trees and soils during leaf blight outbreak season in *Eucalyptus* plantations in southern China. In this study, 482 *Calonectria* isolates obtained from diseased *Eucalyptus* trees and soils under these trees in eight sampling sites in three provinces were identified by DNA sequence analyses of *tef1*, *tub2*, *cmdA*, and *his3* gene regions. Six species residing in three species complexes were identified: *Calonectria pseudoreteaudii* and *C. acaciicola* in the *Calonectria reteaudii* species complex; *C. hongkongensis*, *C. aconidialis*, and *C. chinensis* in *C. kyotensis* species complex; and *C. auriculiformis* in *C. cylindrospora* species complex. The habitats of *Calonectria* in different species complexes differed, *C. reteaudii* species complex inhabits in both diseased trees and soils, *C. kyotensis* species complex only in soils. The Calonectria leaf blight in the sampled regions was caused by species in the *C. reteaudii* species complex but not by the species in the *C. kyotensis* species complex. These findings suggest that the species in the *C. reteaudii* species complex should receive more attention in disease management, as they are the primary cause of the disease in the sampled regions.

Key words: Calonectria leaf blight, *Eucalyptus* disease, forest pathogens, fungal ecology, phylogeny

Introduction

The eucalypts, commonly known as gum trees, include the genera *Angophora*, *Corymbia*, and *Eucalyptus*, with more than 800 species, of which *Eucalyptus* spp. are the most numerous (Thornhill et al. 2019). *Eucalyptus* species are widely cultivated as commercial trees in Southeast Asia, Brazil, China, Australia, India, Europe, and South Africa due to their ability of fast-growing, adaptability, and versatility (Xie and Du 2019). In China, *Eucalyptus* plantations cover an area of approximately 5.46 million hm^2, accounting for approx. 2.5% of the country's total forest area, and provide one-third of the country's timber production (Xie et al. 2017; Xie and Du 2019).

The Eucalyptus leaf blight, caused by *Calonectria* spp., is considered one of the most severe diseases affecting *Eucalyptus* plantations, especially in Asia and South America (Crous 2002; Rodas et al. 2005; Alfenas et al. 2015; Pham et al. 2019, 2022a, 2022b; Wang and Chen 2020; Li et al. 2023a; Liang et al. 2023). The disease initially presents as water-soaked and light gray lesions of the middle and lower leaves. As it rapidly spreads, the lesions progress to light brown color and cover a significant portion of the leaf blade, ultimately leading to defoliation and even the death of the entire tree under highly favorable environmental conditions (Old et al. 2003; Rodas et al. 2005; Wang and Chen 2020; Wu and Chen 2021; Liang et al. 2023).

Severe outbreaks of Calonectria leaf blight have significantly impacted the growth of *Eucalyptus* plantations in southern China, resulting in substantial economic losses (Zhou and Wingfield 2011; Wang and Chen 2020; Wu and Chen 2021; Li et al. 2023a; Liang et al. 2023). The disease was initially observed in an *Eucalyptus* nursery located in Hainan Province in 1985, which resulted in significant mortality among *Eucalyptus* seedlings (Feng and Zheng 1986). In recent years, leaf blight caused by *Calonectria* species has been observed and confirmed in plantation in Fujian, Guangdong, Guangxi, and Hainan Provinces (Chen et al. 2013; Wang and Chen 2020; Wu and Chen 2021; Li et al. 2023b; Liang et al. 2023). The *Calonectria* species that are frequently isolated from diseased *Eucalyptus* trees in China include *C. acaciicola*, *C. pseudoreteaudii*, and *C. queenslandica* (Wang and Chen 2020; Wu and Chen 2021; Li et al. 2023a; Liang et al. 2023).

Calonectria has been detected not only in *Eucalyptus* tissues (mainly from tree leaves, as well as tree shoots and seedling stems) but also in soils under diseased trees and seedlings in China (Li et al. 2017, 2023a; Wang and Chen 2020; Liang et al. 2023). Presently, 26 *Calonectria* species associated with *Eucalyptus* have been identified and reported, including 19 species isolated from diseased leaves, 17 species isolated from soils associated with *Eucalyptus*, and 10 species isolated from both diseased tissues and soils associated with *Eucalyptus* (Lombard et al. 2010c; Li et al. 2017; Liu et al. 2020, 2021; Wu and Chen 2021; Zhang et al. 2022; Liang et al. 2023; Liu and Chen 2023).

Calonectria species have been frequently isolated from diseased *Eucalyptus* trees and soils in their plantations (Liu et al. 2020, 2021; Wu and Chen 2021; Li et al. 2023b; Liu and Chen 2023). However, only two studies were conducted to understand the species diversity and distribution characteristics of *Calonectria*, both from diseased plantation *Eucalyptus* trees and soils under these trees (Wu and Chen 2021; Li et al. 2023b). These studies were conducted solely in one *Eucalyptus* plantation (Wu and Chen 2021), or in a limited number of sampling regions, and there are significant differences in the number of samples between diseased trees and the soil under these trees (Li et al. 2023b). As a result, the distribution patterns of *Calonectria* species associated with diseased *Eucalyptus* trees and soils under these trees are still unclear. The purpose of this study was to comprehensively understand the distribution characteristics of *Calonectria* species related to diseased leaves and soil habitats during leaf blight outbreak season in *Eucalyptus* plantations in southern China. This was achieved by systematically procuring sampled collections of *Calonectria* from eight Calonectria leaf blight outbreak *Eucalyptus* plantations in three provinces in southern China.

Materials and methods

Disease survey, sample collection, and fungal isolation

In September 2021, we conducted several extensive surveys of the disease caused by *Calonectria* species in *E. urophylla* hybrid plantations in Guangdong, Guangxi, and Hainan Provinces in southern China. After the surveys, eight plantations were selected for sampling (Fig. 1). At each of the eight plantations, the trees were one-year-old, and the disease of *Calonectria* leaf blight occurred for about a month. The disease symptoms of Calonectria leaf blight were observed on 60%–80% of trees in each plantation (Fig. 2A, B) typically included leaf spots and blight (Fig. 2C), which resulted in defoliation (Fig. 2D). Depending on the plantation area, a number of diseased trees were selected for diseased leaf sampling. These trees were randomly distributed across each plantation. Three to five fresh symptomatic leaves were collected from each sampled tree. The same number of soil samples was collected under it from the upper 0–20 cm soil profile by removing the thick layer of leaf litter, as described by Liu and Chen (2023). The diseased leaf and soil samples were taken to our laboratory for further study.

To induce *Calonectria* sporulation on leaf samples, one diseased leaf of each sampled tree with typical symptoms of Calonectria leaf blight was selected for incubation in a moist petri dish chamber at room temperature until

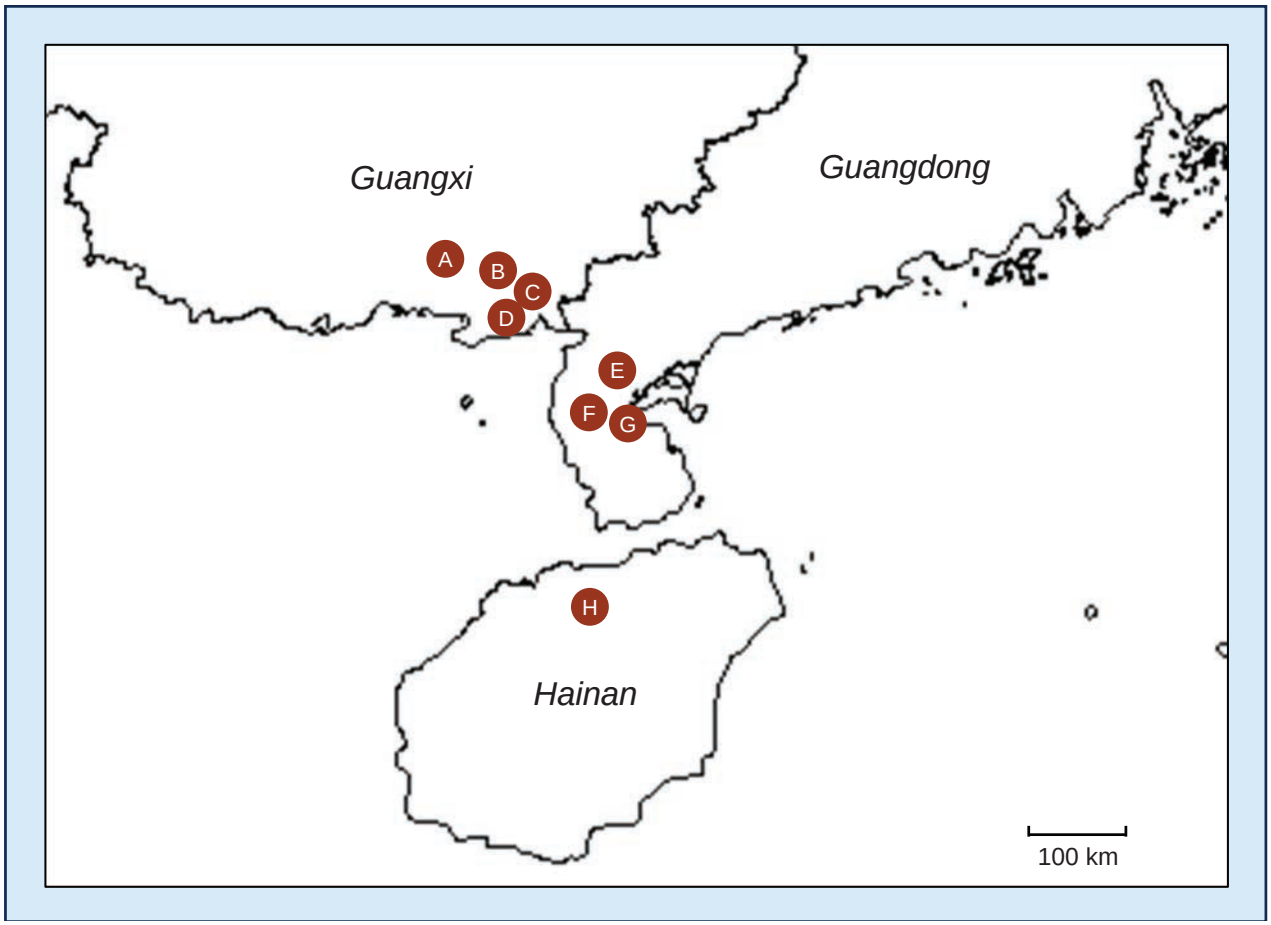

Figure 1. Locations of the eight sampled plantations in the Guangxi (sites **A, B, C, D**), Guangdong (sites **E, F, G**), and Hainan (site **H**) provinces in southern China.

Figure 2. Diseased leaves and soil samples at plantations of a *Eucalyptus urophylla* hybrid in southern China **A, B** leaf spot and blight caused by *Calonectria* species were observed on 60%–80% of the trees in the plantations **C** blighted and dried dead leaves **D** leaves that were dying and drying, resulting in defoliation in the plantation.

the conidiophores were observed. The development of *Calonectria* strains in soil samples was induced by using *Medicago sativa* (alfalfa) seeds, as described by Liu and Chen (2023). The single conidia from conidial masses of *Calonectria* that sporulated from the diseased leaf or soil samples were transferred to 2% (v/v) malt extract agar (MEA) also following Wu and Chen's protocol (2023). One isolate with typical morphological characteristics of the conidiophores

of *Calonectria*, was isolated from each diseased leaf sample or soil sample. Occasionally, two *Calonectria* isolates were isolated from each sample when the isolates with different morphological vesicles were observed. All obtained single conidium cultures were deposited in the Culture Collection (CSF) at the Research Institute of Fast-growing Trees (RIFT), Chinese Academy of Forestry (CAF), Zhanjiang, Guangdong Province, China.

DNA extraction, PCR amplification, and sequencing

The obtained *Calonectria* isolates were cultivated in a 2% MEA medium for a week at room temperature for total genomic DNA extraction. The mycelia were scraped from the cultures. The total genomic DNA of each isolate was extracted using the cetyltrimethylammonium bromide (CTAB) method, as described by van Burik et al. (1998). Four gene regions, namely the translation elongation factor 1-alpha (*tef1*), β-tubulin (*tub2*), calmodulin (*cmdA*), and histone H3 (*his3*), were amplified using the primer pairs and PCR protocols described by Liu et al. (2020). All PCR products were Sanger sequenced in both directions by the same primers used for PCR amplification. The PCR products were sequenced by the Beijing Genomics Institute, Guangzhou, China. All initial sequences were edited using Geneious v.7.1.8 (Kearse et al. 2012). The sequences obtained in this study were deposited in GenBank (http://www.ncbi.nlm.nih.gov).

Phylogenetic analyses

The *tef1* and *tub2* regions were sequenced for all *Calonectria* isolates selected for identification in the current study. All these isolates were preliminarily identified through standard nucleotide BLAST searches in the NCBI database (https://blast.ncbi.nlm.nih.gov/) using the *tef1* and *tub2* sequences. Based on their preliminary identification, representative isolates were selected for sequencing the additional gene regions of *cmdA* and *his3*. Based on the combined genotype of *tef1*, *tub2*, *cmdA*, and *his3* sequences, representative isolates presenting all genotypes obtained in this study were used for molecular identification. Sequences of the isolates from the type specimens of all the published species in the preliminarily identified *Calonectria* species complexes were used for phylogenetic analyses. The sequence datasets were aligned using online MAFFT v. 7 (http://mafft.cbrc.jp/alignment/server/) with the FFT-NS-i strategy (slow; interactive refinement method) (Katoh and Standley 2013). The aligned sequence datasets were manually edited and cut using MEGA v. 7.0 software (Kumar et al. 2016).

The sequence datasets of each gene region and the combination of four gene regions were performed on Maximum likelihood (ML) and Bayesian inference (BI) phylogenetic analyses using CIPRES Science Gateway v. 3.3. For the BI analyses, the most suitable models of the five sequence databases were carried through the jModelTest v. 2.1.5 (Posada 2008). Both ML and BI analyses were completed using online software, RaxML v. 8.2.12 (Stamatakis 2014) and MrBayes. v. 3.2.7 (Ronquist et al. 2012), respectively, as described by Wu and Chen (2023). Phylogenetic trees were viewed via FigTree v 1.4.2 and MEGA v. 7 for BI and ML trees, respectively.

Results

Sample collection and fungal isolation

After a comprehensive collection of samples across eight sites (A–H) in Guangdong, Guangxi, and Hainan Provinces of southern China, a total of 802 samples were collected. These included 401 diseased leaf samples from 401 trees, and 401 soil samples (Table 1, Figs 1, 2). At each sampling site, 39–62 diseased leaf samples, and the same number of soil samples were collected.

Calonectria isolates were obtained from leaf samples from the diseased trees from the eight sampling sites, except for one of the 62 samples from site A and one of the 50 samples from site G. The proportion of diseased leaf samples successfully obtained from *Calonectria* ranged from 98% to 100% for the eight sampling sites (avg. 99.5%). Each isolate was obtained from a single *Calonectria* diseased leaf sample, except for 54 *Calonectria* isolates from 50 such samples at site H. This is because four diseased leaf samples at site H exhibited differing vesicle morphologies, therefore, two isolates were obtained from each of them (Table 1).

A relatively large proportion of *Calonectria* isolates were obtained from the soil samples from the eight sites, except for sites F and G (Guangdong Province). The proportion of soil samples with *Calonectria* ranged from 2% (site G) to 100% (site H) (avg. 51.1%). Each isolate was obtained from a single *Calonectria* soil sample at sites B, E, F, and G, while more than one isolate was obtained from some of the soil samples at the sites A, C, D, and H where isolates with different morphologies of the conidia or vesicles were observed (Table 1).

In total, 642 isolates with typical morphological characteristics of *Calonectria* were obtained. These included 403 isolates from the 401 diseased leaf samples and 239 isolates from the 401 soil samples (Table 1).

Table 1. The number of samples and *Calonectria* spp. obtained from *Eucalyptus* plantations at eight sampling sites.

Sequencing

Calonectria isolates were obtained from a relatively large proportion of the samples, from both the diseased trees and soils, at sites A, B, C, D, E, and H. All isolates from sites B, D, E, and H were sequenced. Since sites A, and C are relatively near to B, and D, only partial isolates obtained from diseased trees and soils at sites A, and C were sequenced. Since *Calonectria* was obtained from a small proportion of the soil samples at sites F, and G, all the isolates obtained from soils, and partial isolates obtained from diseased trees at the two sites were sequenced (Table 1). In total, 482 isolates were used to sequence the *tef1* and *tub2* gene regions (Table 1, Suppl. material 1). This included 54 isolates that were also identified by Liang et al. (2023) (Suppl. material 1). Based on the combined genotypes of the *tef1* and *tub2* gene sequences, and the sampling source, 169 isolates were selected for further sequencing of the *cmdA* and *his3* gene regions (Suppl. material 1). A total of 18 genotypes were generated based on the sequences of the *tef1*, *tub2*, *cmdA*, and *his3* regions of the 169 isolates that allowed for their identification. The remaining 313 isolates were identified based on *tef1* and *tub2* gene regions exclusively.

Phylogenetic analyses

To analyze their phylogenetic relationships, one or two isolates representing single genotype were selected that resulted in selection of 29 isolates representing 18 genotypes in total (Suppl. material 1). Additionally, the sequences from 90 isolates, including all ex-type isolates of all the *Calonectria* species of their respective species complexes, corresponding to 52 published *Calonectria* species, were retrieved from GenBank (Table 2). These sequences were used in phylogenetic analyses of the four individual gene regions and a combination of them.

The sequenced isolates yielded approximately 500 bp for *tef1*, 560 bp for *tub2*, 680 bp for *cmdA*, and 430 bp for *his3* gene regions. The model for each gene region was selected based on jModeltest v. 2.1.5. The TIM2+I+G, HKY+I+G, TrN+I+G, HKY+I+G, and TIM2+I+G models were selected for *tef1*, *tub2*, *cmdA*, *his3*, and the consolidated dataset, respectively. The topological structures generated from BI analyses were similar to those generated from ML analyses for each dataset. The ML trees displayed bootstrap values from ML and the posterior probabilities from BI are shown in Fig. 3, Suppl. materials 2–5.

The 29 *Calonectria* isolates were clustered into six distinct groups (Groups A–F) based on the phylogenetic analyses of the four gene regions' combination (Fig. 3). Among them, isolates in Group A and Group B belong to the *C. reteaudii* complex. Isolates in Group A were clustered with or closely related to *C. acaciicola*, *C. pseudoreteaudii*, *C. reteaudii*, or *C. guangdongensis* in the *tef1*, *cmdA*, and *his3* trees (Suppl. materials 2, 4, 5), and with *C. acaciicola* in the *tub2* tree (Suppl. material 3). The *tef1*/*tub2*/*cmdA*/*his3* tree confirmed that isolates in Group A were most closely related to *C. acaciicola* (Fig. 3), and thus they were accepted as belonging to this species. Isolates in Group B were clustered with, or most closely related to, *C. pseudoreteaudii* in each of the *tef1*, *tub2*, *cmdA*, *his3*, and *tef1*/*tub2*/*cmdA*/*his3* trees (Fig. 3, Suppl. materials 2–5). Thus, isolates in Group B are referred as *C. pseudoreteaudii*.

Table 2. *Calonectria* spp. isolates from the published studies used for phylogenetic analyses in this study.

[d] *tef1*: translation elongation factor 1-alpha; *tub2*: β-tubulin; *cmdA*: calmodulin; *his3*: histone H3.
[e] N/A: information is not available.

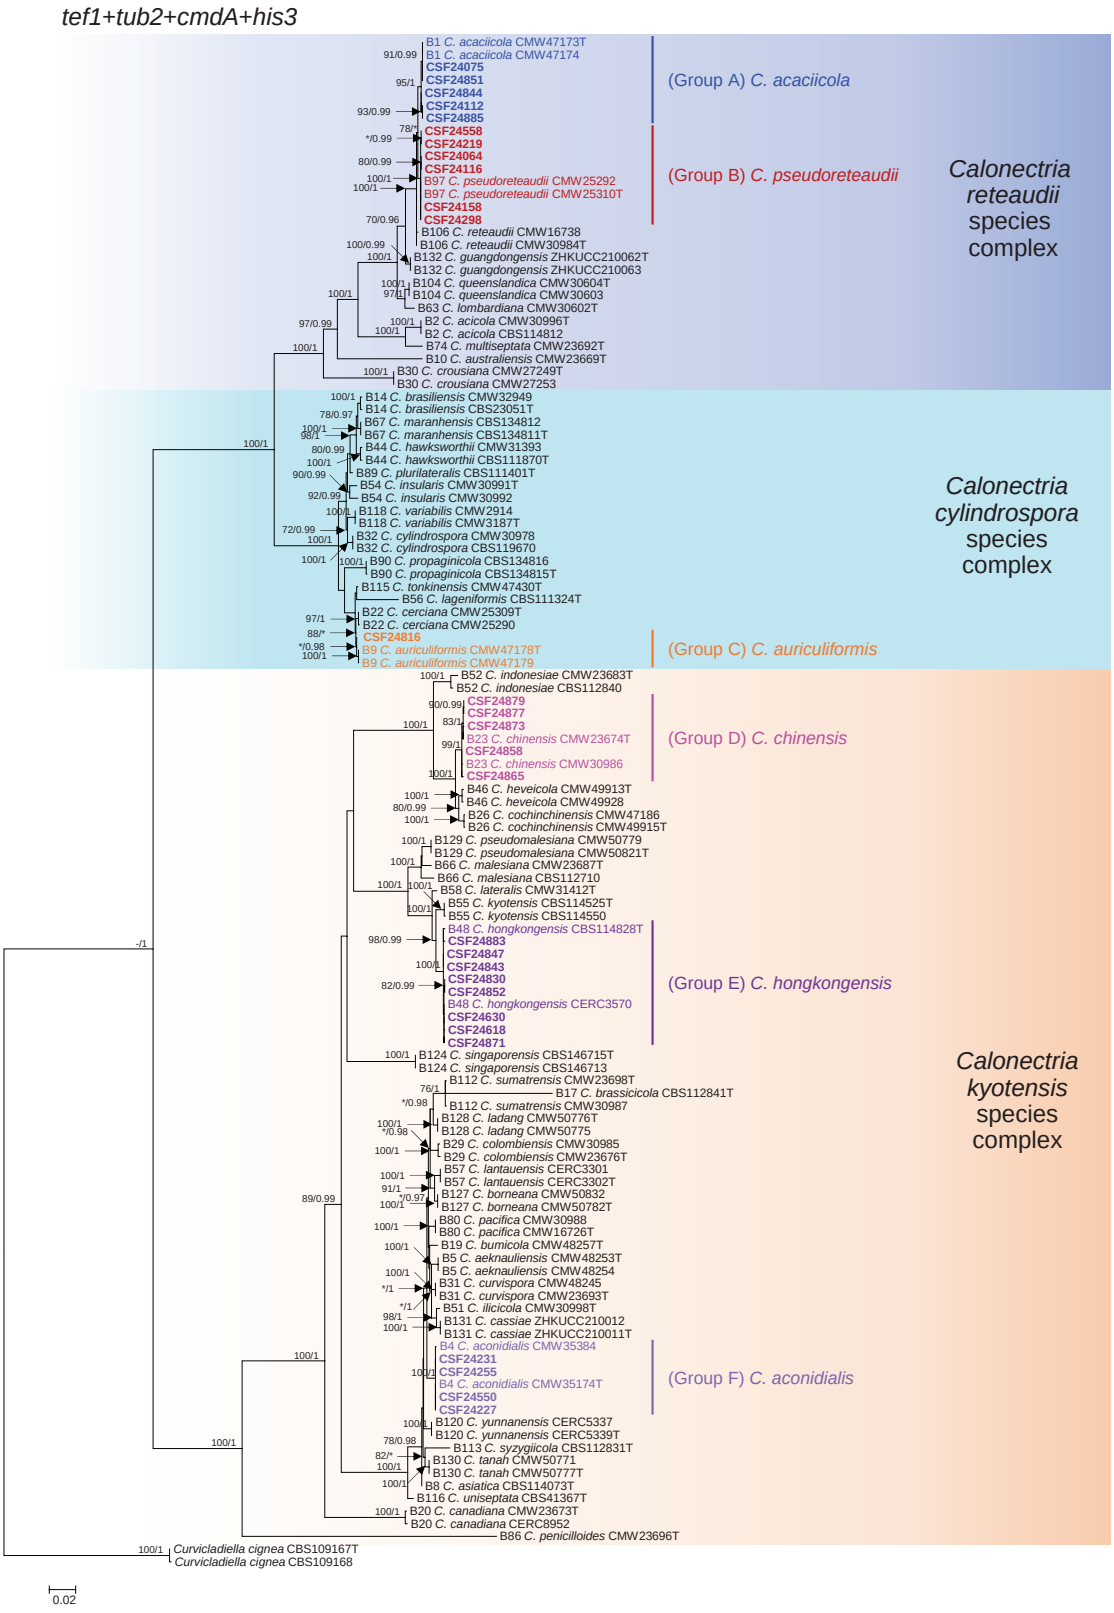

Figure 3. Phylogenetic tree of *Calonectria* species based on maximum likelihood (ML) analyses of a combined DNA dataset of *tef1*, *tub2*, *cmdA*, and *his3* gene sequences. Bootstrap support values ≥ 70% for ML and posterior probability values ≥ 0.95 for Bayesian inference (BI) analyses are presented above the branches as ML/BI. Bootstrap values < 70% or probability values < 0.95 are marked with "*," and absent analysis values are marked with "-". Ex-type isolates are marked with "T." Isolates sequenced in this study are highlighted in bold. The outgroup taxon was *Curvicladiella cignea* (CBS 109167 and CBS 109168).

Isolate CSF24816 (Group C) was grouped in the *C. cylindrospora* species complex (Fig. 3, Suppl. materials 2–5). It was clustered with *C. auriculiformis* in the *tef1* tree, with *C. cerciana* in the *tub2* tree, with *C. cerciana* and *C. tonkinensis* in the *cmdA* tree, and with *C. auriculiformis*, *C. cerciana*, and *C. tonkinensis* in the *his3* tree (Suppl. materials 2–5). It was most closely related to *C. auriculiformis* in the *tef1/tub2/cmdA/his3* tree (Fig. 3), thus the isolate CSF24816 was identified as *C. auriculiformis*.

Isolates in Groups D, E, and F resided in the *C. kyotensis* species complex based on the phylogenetic trees of *tef1*, *tub2*, *cmdA*, *his3*, and *tef1/tub2/cmdA/his3* (Fig. 3, Suppl. materials 2–5). Isolates in Group D, Group E, and Group F were consistently clustered with or most closely related to *C. chinensis*, *C. hongkongensis*, and *C. aconidialis*, respectively (Fig. 3, Suppl. materials 2–5). Therefore, isolates in Group D, Group E, and Group F were identified as *C. chinensis*, *C. hongkongensis* and *C. aconidialis*, respectively.

Calonectria distribution associated with diseased leaves and soil in *Eucalyptus* plantations

The 482 *Calonectria* isolates used for molecular identification in the current study were identified as six species, which resided in three species complexes. The six species were *C. pseudoreteaudii* (411 isolates, 85.27%), *C. acaciicola* (42 isolates, 8.71%), *C. hongkongensis* (16 isolates, 3.32%), *C. aconidialis* (seven isolates, 1.45%), *C. chinensis* (five isolates, 1.04%), and *C. auriculiformis* (one isolate, 0.21%) (Fig. 4).

At each of the eight sampling sites, *C. pseudoreteaudii* was dominant in the samples collected from both the diseased trees and soil under these trees, particularly at sites A–G located on the mainland of China. *Calonectria acaciicola* isolates were obtained from site H in Hainan Province, and this species was also frequently isolated from both diseased trees and soil. The other four *Calonectria* species, *C. hongkongensis*, *C. aconidialis*, *C. chinensis*, and *C. auriculiformis*, were only isolated from samples collected from soils (Table 1, Figs 4, 5).

When considering the species complexes associated with diseased leaves and soils, all *Calonectria* isolates obtained from diseased trees resided in the *C. reteaudii* species complex; and 14.14% of *Calonectria* isolates obtained from soils resided in the *C. kyotensis* species complex. All isolates residing in the *C. kyotensis* species complex were obtained from soils. For the isolates residing in the *C. reteaudii* species complex, 62.69% of the isolates come from diseased trees and 37.31% were from soil samples (Table 1, Fig. 5).

Discussion

In this study, a systematic and comprehensive investigation of Calonectria leaf blight occurring on *Eucalyptus* plantations in a wide geographic range in southern China was conducted. The results of this study clearly showed that the *Calonectria* species in the *C. cylindrospora* species complex was occasionally distributed in *Eucalyptus* plantations. *Calonectria* species in both the *C. reteaudii* species complex and *C. kyotensis* species complex were widely distributed. The distribution patterns of *Calonectria* species in the *C. reteaudii* species complex and *C. kyotensis* species complex were related to diseased leaves and soil habitats during leaf blight outbreak season in *Eucalyptus* plantations in southern China.

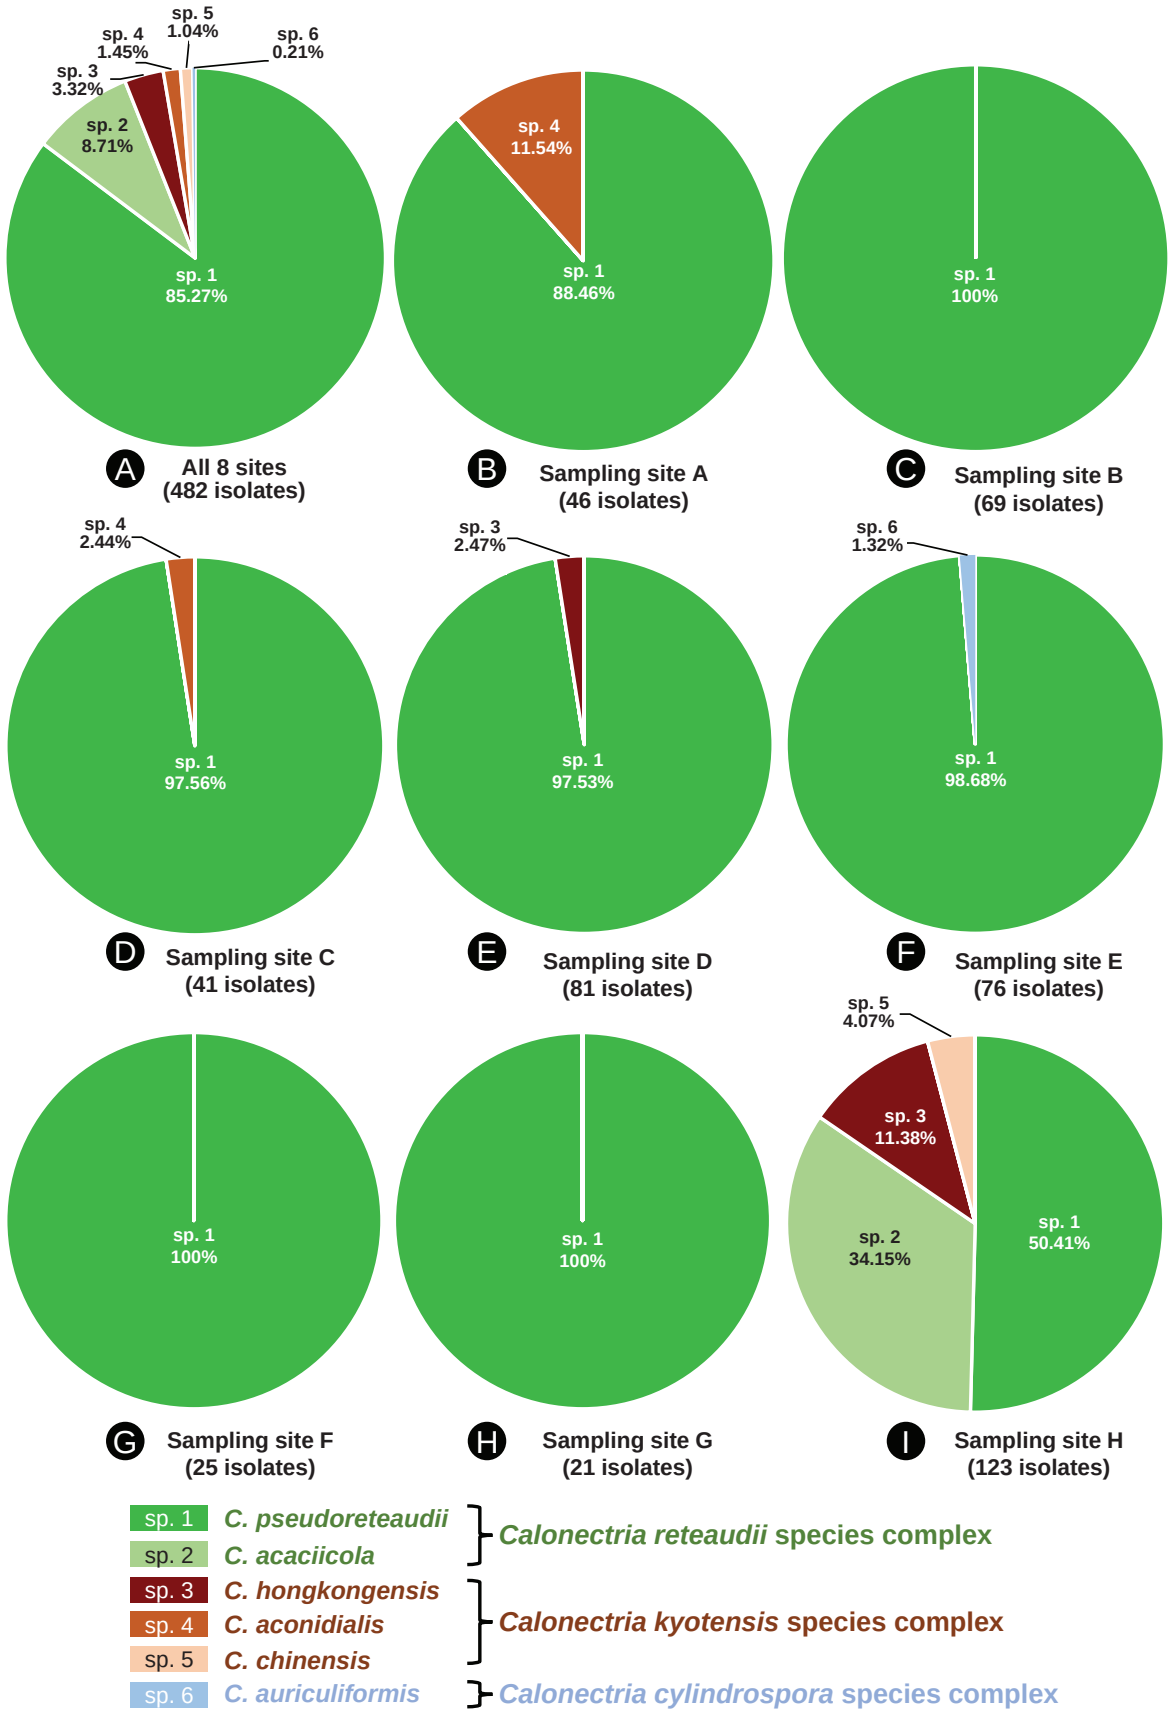

Figure 4. The isolate number and percentage of each *Calonectria* species at the eight sampling sites. "sp. 1, 2, 3, 4, 5, 6" indicate the six *Calonectria* species **A** isolates and species obtained from all eight sites **B-I** isolates and species obtained from a particular site (sites **A–H**).

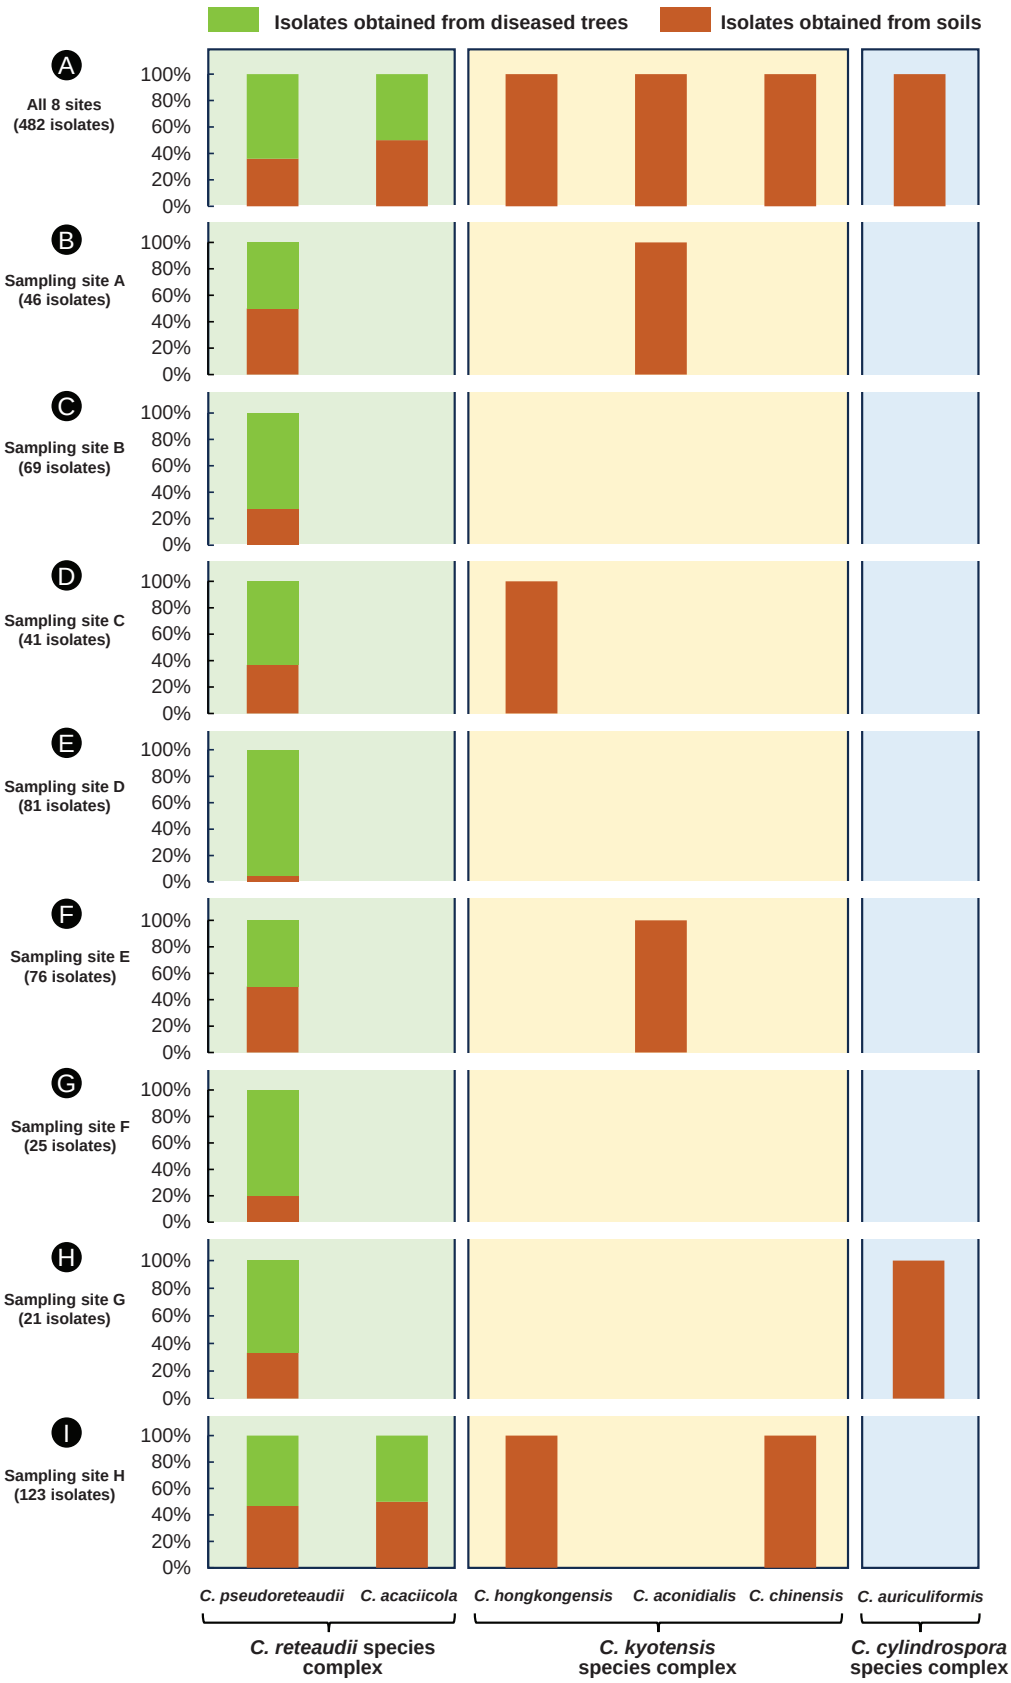

Figure 5. Histogram showing the proportions of each of the six *Calonectria* species reside in three species complexes isolated from diseased leaves and soil at the eight sampling sites. The histograms in green and orange indicated isolates obtained from diseased trees and soils, respectively **A** species obtained from all the eight sites **B–I** species obtained from a particular site (sites **A–H**).

The results of this study showed that all isolates obtained from diseased trees resided in the *C. reteaudii* species complex, which indicated that they are the causal agents of Calonectria leaf blight at the sampled sites in China. Moreover, *C. pseudoreteaudii* was the dominant species of all the eight sampling sites in the three provinces. This was consistent with previous studies in which *C. pseudoreteaudii* was frequently obtained from diseased *Eucalyptus* trees in Guangdong, Guangxi, Fujian, and Hainan Provinces in southern China (Chen et al. 2013; Wang and Chen 2020; Wu and Chen 2021; Li et al. 2023a; Liang et al. 2023). *Calonectria acaciicola* was only isolated from site H in Hainan Province in this and a previous study by Liang et al. (2023). Furthermore, inoculation results from previous studies indicated that both *C. pseudoreteaudii* and *C. acaciicola* were highly virulent to the tested *Eucalyptus* genotypes (Liang et al. 2023). *C. pseudoreteaudii* is one of the main causal agents of Calonectria leaf blight widely observed in southern China, and *C. acaciicola* is causal agent of the disease in Hainan Province in particular.

It is still unclear whether the species in the *C. reteaudii* complex are soil-borne or not. The results of the previous studies consistently indicated that species in the *C. reteaudii* complex can survive in the soils, at least for a certain time (Crous 2002; Liu et al. 2021). Both *C. pseudoreteaudii* and *C. acaciicola* were frequently isolated from soils under the diseased trees in this study. Results of the previous research confirmed that *Calonectria* species in the *C. reteaudii* species complex were frequently isolated from soils under diseased *Eucalyptus* trees in southern China (Wu and Chen 2021; Li et al. 2023b). A recent population study showed that the genetic diversity of the *C. pseudoreteaudii* isolates obtained from diseased leaves was higher than that of the *C. pseudoreteaudii* isolates obtained from the soil in one *Eucalyptus* plantation, and the *C. pseudoreteaudii* isolates in soil may spread from diseased leaves (Wu et al. 2023). The results of the current study highlight that *C. pseudoreteaudii* from the soils in *Eucalyptus* plantations also needs to be carefully monitored for disease management purposes. It is necessary to clarify whether *Calonectria* in the *C. reteaudii* species complex is soil-borne or not and further understand the sources and dispersal pathways of the pathogens from this complex.

Previous studies showed that the species in the *C. kyotensis* complex were widely isolated from soils, both in natural forests and commercial plantations (Liu et al. 2021, 2022; Wu and Chen 2021, 2023; Li et al. 2023b; Liu and Chen 2023), and a relatively small number of isolates were isolated from susceptible *Eucalyptus* leaves (Li et al. 2023a; Liang et al. 2023). The research in this study indicated that all isolates residing in the *C. kyotensis* species complex were obtained from soils but not from diseased trees. Moreover, the results of this study revealed that isolates in the *C. kyotensis* species complex may not be the pathogens causing leaf blight in *Eucalyptus*. Further research is needed to clarify their ecological niche since they were also frequently isolated from diseased leaves (Li et al. 2023b; Liang et al. 2023).

Conclusion

This study clarified the distribution patterns of *Calonectria* species complexes related to the *Calonectria* isolated sources of diseased trees and soils during the disease outbreak season. The results of this study clearly showed that all isolates obtained from diseased leaves resided in the *C. reteaudii* species com-

plex, and species in the *C. reteaudii* species complex were widely distributed in diseased leaves and soils. All the isolates residing in the *C. kyotensis* species complex were obtained from soils. This indicated that species in the *C. kyotensis* species complex are soil inhabitants. These results highlight that *Calonectria* species in the *C. reteaudii* species complex, but not in the *C. kyotensis* species complex, are the causal agents of Calonectria leaf blight in southern China. More attention should be paid to the causal agents of Calonectria leaf blight, especially *C. pseudoreteaudii*, with a wide geographic distribution during the disease outbreak season, for disease management in the future.

Abstract

Two new *Cordyceps*-like species, *Perennicordyceps zongqii* and *Purpureocillium zongqii*, isolated from a larva and soil, are introduced. Morphological comparisons and phylogenetic analyses based on multigene datasets (ITS, LSU, *RPB2* and *TEF*) support the establishment of the new species. Moreover, new species in the families Polycephalomycetaceae and Ophiocordycipitaceae were introduced into Tiankeng and the valley for the first time. Further attention needs to be paid to the diversity of other *Cordyceps*-like fungi in the special eco-environment of the karst region.

Key words: *Cordyceps*-like species, morphology, Ophiocordycipitaceae, phylogenetic analysis, Polycephalomycetaceae

Introduction

Cordyceps-like fungi, also known as *Cordyceps* sensu lato, refers to species belonging to Hypocreales, Sordariomycetes and Ascomycota, and contains all the species in the families Cordycipitaceae, Ophiocordycipitaceae and Polycephalomycetaceae, as well as some species in the family Clavicipitaceae (Li et al. 2021; Xiao et al. 2023). Currently, more than 2000 species of *Cordyceps*-like fungi have been reported worldwide, while there are just over 300 species in China (Chen et al. 2021d; Li et al. 2023, http://www.indexfungorum.org/Names/Names.asp, 17 August, 2024). Therefore, more attention needs to be paid to the diversity of *Cordyceps*-like fungi in China.

The karst region, especially in southern China, preserves unique, large-scale, and continuously distributed primitive forests with extremely rich biodiversity. The complex ecological environment and special geographical conditions in the region have become shelters for many unique species (Özkan et al. 2010; Su et al. 2017). Previous studies have shown that the resources of *Cordyceps*-like fungi in karst areas are very abundant (Zhu et al. 2004; Song et al. 2011). In recent years, Yunnan and Guizhou Province have become hot areas for research on *Cordyceps*-like fungi

(Ming et al. 2021; Chen et al. 2021a, b, c, 2022a, b, c, 2023; Qu et al. 2021; Dong et al. 2022; Wang et al. 2022, 2024a; Zhou et al. 2022; Zou et al. 2022; Peng et al. 2023, 2024; Tang et al. 2023a, b, c; Xiao et al. 2023, 2024; Zhang et al. 2023; Dai et al. 2024), and the majority of sampling locations were located in karst forest habitats. However, there are also some special habitats in karst areas, such as Tiankeng and the valley, because of its unique geological landscape, which creates a microclimate distinct from its surrounding area and a unique habitat suitable for biological survival. Unfortunately, the *Cordyceps*-like fungi in these habitats have been neglected.

Chen et al. (2022b, 2023) reported ten new *Cordyceps*-like fungi in the family Cordycipitaceae from Tiankeng and the valley. Two new genera and three new species in the family Clavicipitaceae were introduced from the valley by Chen et al. (2022a). However, *Cordyceps*-like fungi were rarely reported in other families from Tiankeng or the valley. Besides, *Cordyceps*-like fungi was omnipresent in the obtaining nutrients and was abundant in the soil (Chen et al. 2022a, Quesada-Moraga et al. 2007). Unfortunately, few reports exist about the *Cordyceps*-like fungi from the soil of Tiankeng or the valley.

During a survey of *Cordyceps*-like fungi associated with insects and soil from Southwest China, the infected specimen and soil were collected, and strains were isolated. After detailed multiloci phylogenic analysis and morphological observations, two new species were identified as belonging to the family Polycephalomycetaceae and Ophiocordycipitaceae.

Materials and methods

Specimen and soil collection, isolation

The specimen and soil (for the photo descriptions of the sampling site see Suppl. materials 1–5) were collected from Mayao River Valley (26°22'8.3748"N, 107°23'16.96"E), Duyun City, Qiannan Buyei and Miao Autonomous Prefecture and Monkey-Ear Tiankeng (27°5'12.138"N, 107°0'48.42"E), Kaiyang County, Guiyang, Guizhou Province, on 1 May 2022 and 19 July 2023. The samples were placed in an ice box and brought to the laboratory. Specimens were preserved in the refrigerator at 4 °C until further processing. The surface of each arthropod body was rinsed with sterile water, followed by sterilization with 75% ethanol for 3–5 s and rinsing again three times with sterilized water. After drying on sterilized filter paper, a piece of the synnemata, mycelium or sclerotia was cut from the specimen and inoculated on agar plates of potato dextrose agar (PDA) or PDA modified by the addition of 1% w/v peptone containing 0.1 g/l streptomycin and 0.05 g/l tetracycline (Chen et al. 2019). After fungal colonies emerged from the inoculated samples, a piece of mycelium from the colony edge was transferred onto new agar plated and cultured at 25 °C for 14 days under 12 h light/12 h dark conditions (Zou et al. 2010). Then 2 g collected soil were placed into a sterile conical flask containing 20 ml sterile water and thoroughly shaken using a Vortex vibration meter. Next, the suspension was diluted to a concentration of 10^{-3}. Subsequently, 1 ml of the diluted sample was added to a sterile Petri dish and mixed with Sabouraud's dextrose agar (SDA; peptone 10 g/l, dextrose 40 g/l, agar 20 g/l, 3.3 ml of 1% Bengal red aqueous solution) medium containing 50 mg/l penicillin and 50 mg/l streptomycin. After the plates were incubated at 25 °C for 1–2 weeks, single colonies were transferred

from the plates to new PDA plates (Wang et al. 2024b). The holotypes and extypes were deposited at the Institute of Fungus Resources, Guizhou University (formally Herbarium of Guizhou Agricultural College; code, GZAC), Guiyang City, Guizhou, China. MycoBank numbers have been obtained as outlined in MycoBank (http://www.MycoBank.org) (Crous et al. 2004).

Morphological studies

Colony morphology was determined on PDA cultures incubated at 25 °C for 14 days and the growth rate, the presence of octahedral crystals and the colony colours (surface and reverse) were observed. To investigate the microscopic characteristics, a little of the mycelia was picked up from the colony and mounted in lactophenol cotton blue or 20% lactate acid solution and the asexual morphological characteristics (e.g., conidiophores, phialides and conidia) were observed and measured using a Leica DM4 B microscope. Twenty measurements were recorded for hyphae, conidiophores, phialides and conidium.

DNA extraction, PCR and sequencing

DNA extraction was carried out using a fungal genomic DNA extraction kit (DP2033, BioTeke Corporation) according to Liang et al. (2011). The extracted DNA was stored at −20 °C. Polymerase chain reaction (PCR) was used to amplify genetic markers using the following primer pairs: ITS4/ITS5 for the internal transcribed spacer (ITS) region (White et al. 1990), LR0R/LR5 for 28s large subunit ribosomal (LSU) (Vilgalys and Hester 1990), fRPB2-5F/fRPB2-7cR for RNA polymerase II second largest subunit (*RPB2*) (Liu et al. 1999) and 983F/2218R for translation elongation factor 1 alpha (*TEF*) (Castlebury et al. 2004). The thermal cycle of PCR amplification for these phylogenetic markers was set up following the procedure described by Chen et al. (2021c). PCR products were purified and sequenced at Sangon Biotech (Shanghai) Co. by Sanger dideoxy sequencing. All newly generated sequences were deposited in GenBank and accession numbers were obtained. The sequences used in the study were listed in Table 1.

Sequence alignments and phylogenetic analyses

DNASTAR™ Lasergene (v 6.0) was used to edit DNA sequences in this study. The ITS, LSU, *RPB2* and *TEF* sequences were downloaded from GenBank, based on Xiao et al. (2023), Calvillo-Medina et al. (2021), Luangsa-ard et al. (2011), Chen et al. (2024) and others selected based on BLASTn searches in GenBank. ITS sequences and other loci were aligned and edited by MAFFT v.7.037b (Katoh and Standley 2013) and MEGA6 (Tamura et al. 2013). Combined sequences of ITS, LSU, *RPB2* and *TEF* were obtained using SequenceMatrix v.1.7.8 (Vaidya et al. 2011). The model was selected for Bayesian analysis by ModelFinder (Kalyaanamoorthy et al. 2017) in PhyloSuite (v1.2.2) software (Zhang et al. 2020).

The combined dataset of ITS, LSU, *RPB2* and *TEF* sequence data (Suppl. materials 1–5) was analyzed using Bayesian inference (BI) and maximum likelihood (ML) methods. For BI, a Markov chain Monte Carlo (MCMC) algorithm was used to generate phylogenetic trees with Bayesian probabilities for the combined sequence datasets using MrBayes v.3.2 (Ronquist et al. 2012).

The Bayesian analysis resulted in 20,001 trees after 10,000,000 generations. The first 4,000 trees, representing the burn-in phase of the analysis, were discarded, while the remaining 16,001 trees were used to calculate posterior probabilities in the majority rule consensus tree. After the analysis was finished, each run was examined if it was greater than 200 using the program Tracer v.1.5 (Drummond and Rambaut 2007) to determine burn-in and confirm that both runs had converged. ML analyses were constructed with IQ-TREE (v 2.0) (Trifinopoulos et al. 2016), using an automatic selection of the model according to BIC.

Results

Phylogenetic analyses

The phylogenetic tree (Fig. 1) was generated to determine the relationship among those new strains and its related species. *Simplicillium lanosoniveum* (J.F.H. Beyma) Zare & W. Gams (CBS 704.86) and *S. lamellicola* (F.E.V. Sm.) Zare & W. Gams (CBS 116.25) were used as the outgroups. The concatenated sequences included 40 taxa and consisted of 3,392 (ITS, 616; LSU, 841; *RPB2*, 1,041; and *TEF*, 894) characters with gaps.

The selected model for ML analysis was TN+F+I+G4. The final value of the highest scoring tree was −15,988.941, which was obtained from an ML analysis of the dataset (ITS, LSU, *RPB2* and *TEF*). The parameters of the rate heterogeneity model used to analyze the dataset were estimated using the following frequencies: A = 0.230, C = 0.288, G = 0.278, T = 0.204; substitution rates AC = 1.00000, AG = 2.57904, AT = 1.00000, CG = 1.00000, CT = 5.70221 and GT = 1.00000, as well as the gamma distribution shape parameter α = 0.805. The selected models for BI analysis were GTR+F+I+G4 (ITS, LSU, *RPB2* and *TEF*). The phylogenetic trees (Fig. 1) constructed using ML and BI analyses were largely congruent and strongly supported in most branches. The new strains DY05421 and DY05422 were clustered into an independent clade in the group of the genus *Perennicordyceps* and have a close relationship with *Perennicordyceps cuboidea* (Kobayasi & Shimizu) Matočec & I. Kušan (NBRC 101740, NBRC 103836 and NBRC 100941) and *P. ryogamiensis* (Kobayasi & Shimizu) Matočec & I. Kušan (NBRC 101751, NBRC 103842 and NBRC 103837). Strains TK041, TK042 were clustered into the group of the genus *Purpureocillium* and have a close relationship with *Purpureocillium lilacinum* (Thom) Luangsa-ard, Houbraken, Hywel-Jones & Samson (CBS 284.36).

Taxonomy

Perennicordyceps zongqii **W.H. Chen, Y.F. Han & J.D. Liang, sp. nov.**
MycoBank No: 855564
Fig. 2

Etymology. In honor of Prof. Zongqi Liang, for his support and guidance in arthropod pathogenic fungi research.

Type. China • Guizhou Province, Qiannan Buyei and Miao Autonomous Prefecture, Duyun City, Mayao River Valley (26°22'8.3748"N, 107°23'16.96"E), on a larva of moth (Lepidoptera), on the leaf litter, 1 May 2022, Wanhao Chen, GZAC DY0542 (holotype), ex-type DY05421.

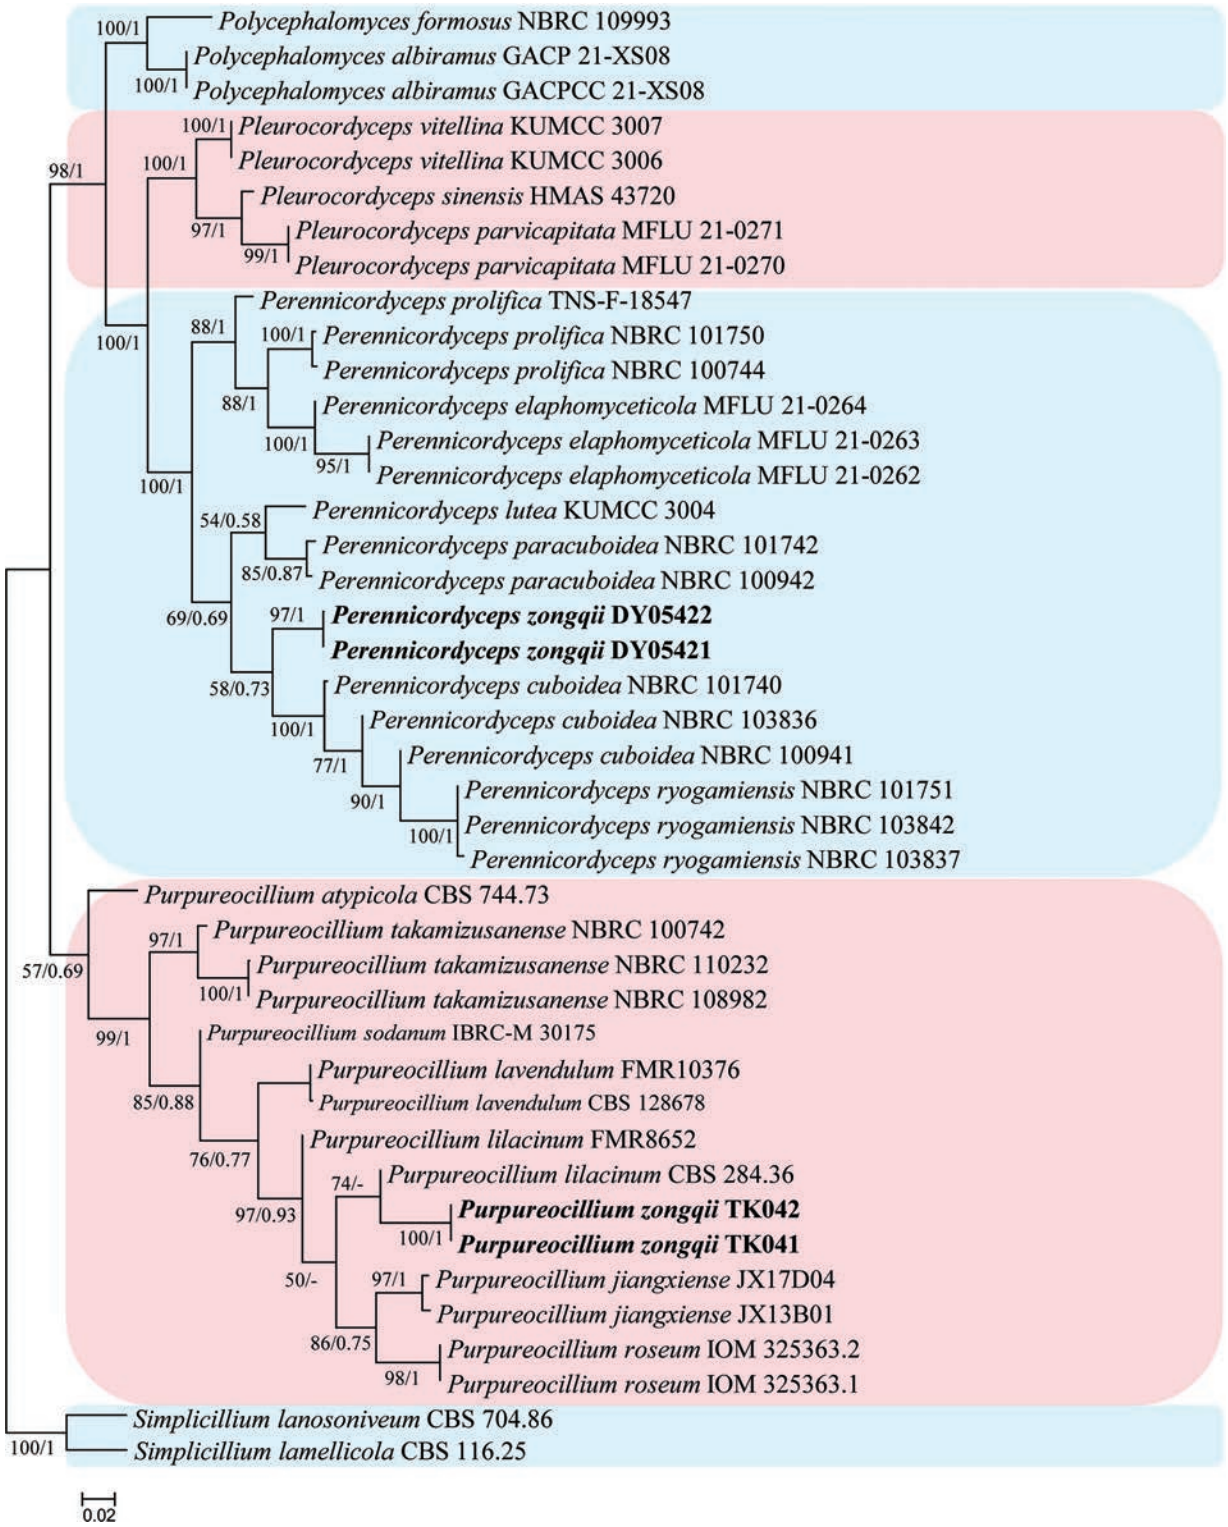

Figure 1. Phylogenetic analysis of the new strains and its related species based on multigene dataset (ITS, LSU, *RPB2* and *TEF*). Statistical support values (≥ 50%/0.5) are shown at the nodes for ML bootstrap support/BI posterior probabilities.

Description. Colonies on PDA, attaining a diameter of 56–59 mm after 14 days at 25 °C, white, consisting of a basal felt, floccose hyphal overgrowth, yellowish in middle; reverse yellow to pale yellowish, light brown to brown in the middle. Hyphae septate, hyaline, yellowish in the middle part of the colony, smooth-walled, 1.1–2.1 µm wide. Conidiophores erect, hyaline, irregular

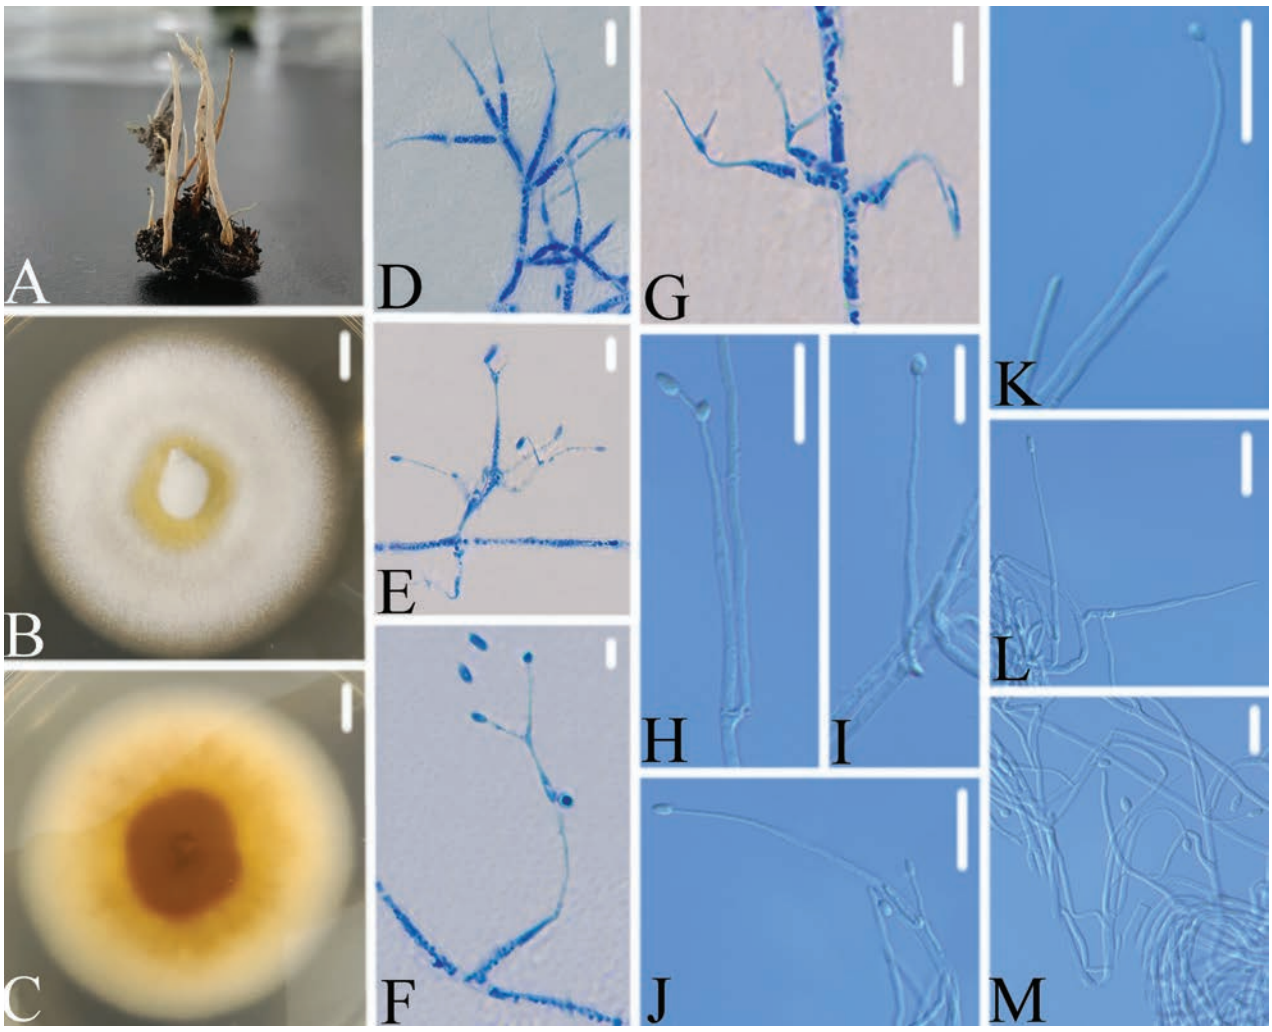

Figure 2. *Perennicordyceps zongqii* **A** infected larva **B**, **C** colony on PDA (**B** obverse, **C** reverse) **D–M** phialides and conidia. Scale bars: 10 mm (**B**, **C**); 10 µm (**D–M**).

branched, with 1–4 phialides. Phialides 29.3–31.1 × 1.5–2.4 µm, hyaline, cylindrical at base, gradually tapering near the apex, holoblastic or branch. Conidia 3.4–4.8 × 2.5–2.7 µm, hyaline, smooth-walled, thin-walled, ellipsoidal to cylindrical, unicellular, acuminate, arranged in chains not observed.

Distribution. Duyun City, Guizhou Province, China.

Host. Larva (Lepidoptera).

Additional strain examined. China • Guizhou Province, Qiannan Buyei and Miao Autonomous Prefecture, Duyun City, Mayao River Valley (26°22'8.3748"N, 107°23'16.96"E). On a larva of moth (Lepidoptera), on the leaf litter, 1 May 2022, Wanhao Chen, DY05422 (living culture).

Notes. Strain DY05421 was easily identified as *Perennicordyceps*, based on the BLASTn result in NCBI. Phylogenetic analyses show that strain DY05421 has close relationships to *P. cuboidea and P. ryogamiensis* (Fig. 1). However, strain DY05421 was easily distinguished from *P. cuboidea* (globose to ellipsoid conidia, 1.3–3.7 × 1.1–2.3 µm; phialide, 18.9–22.2 × 0.8–1.1 µm; substrate, larvae of Coleoptera) by its larger ellipsoidal to cylindrical conidia, larger phialide and the substrate (Ban et al. 2009). Strain DY05421 was easily distinguished from *P. ryogamiensis* (ellipsoid conidia, 2.5–3.9 × 1.0–1.4 µm; phialide, 17.5–55.2 ×

0.8–2.7 µm; substrate, larvae of Coleoptera) by its larger ellipsoidal to cylindrical conidia, smaller phialide and the substrate (Ban et al. 2009). Thus, the morphological characteristics and molecular phylogenetic results support *strain* DY05421 as a new *Perennicordyceps* species and named *Perennicordyceps zongqii*.

Purpureocillium zongqii **W.H. Chen, Y.F. Han & J.D. Liang, sp. nov.**
MycoBank No: 855565
Fig. 3

Etymology. In honor of Prof. Zongqi Liang, for his support and guidance in arthropod pathogenic fungi research.

Type. China • Guizhou Province, Guiyang, Kaiyang County, Monkey-Ear Tiankeng (27°5'12.138"N, 107°0'48.42"E), soil, 19 July 2023, Wanhao Chen, GZAC TK04 (dried holotype), ex-type TK041.

Description. Colonies on PDA, attaining a diameter of 23–25 mm after 14 days at 25 °C, white, consisting of a basal felt, floccose hyphal overgrowth, white; reverse yellowish. Hyphae septate, hyaline, smooth-walled, 1.1–1.9 µm wide. Conidiophores 9.3–12.7 × 2.1–2.4 µm, erect, hyaline, verticillately branched, with 1–4 phialides. Phialides 6.8–11.7 × 2.6–4.0 µm, hyaline, cylindrical at base, gradually tapering near the apex. Conidia 2.7–4.2 × 2.0–2.4 µm, hyaline, smooth-walled, thin-walled, ellipsoidal, unicellular, acuminate, arranged in chains not observed.

Substrate. Soil.

Distribution. Kaiyang County, Guizhou Province, China.

Additional strain examined. China • Guizhou Province, Guiyang, Kaiyang County, Monkey-Ear Tiankeng (27°5'12.138"N, 107°0'48.42"E), soil, 19 July 2023, Wanhao Chen, TK042 (living culture).

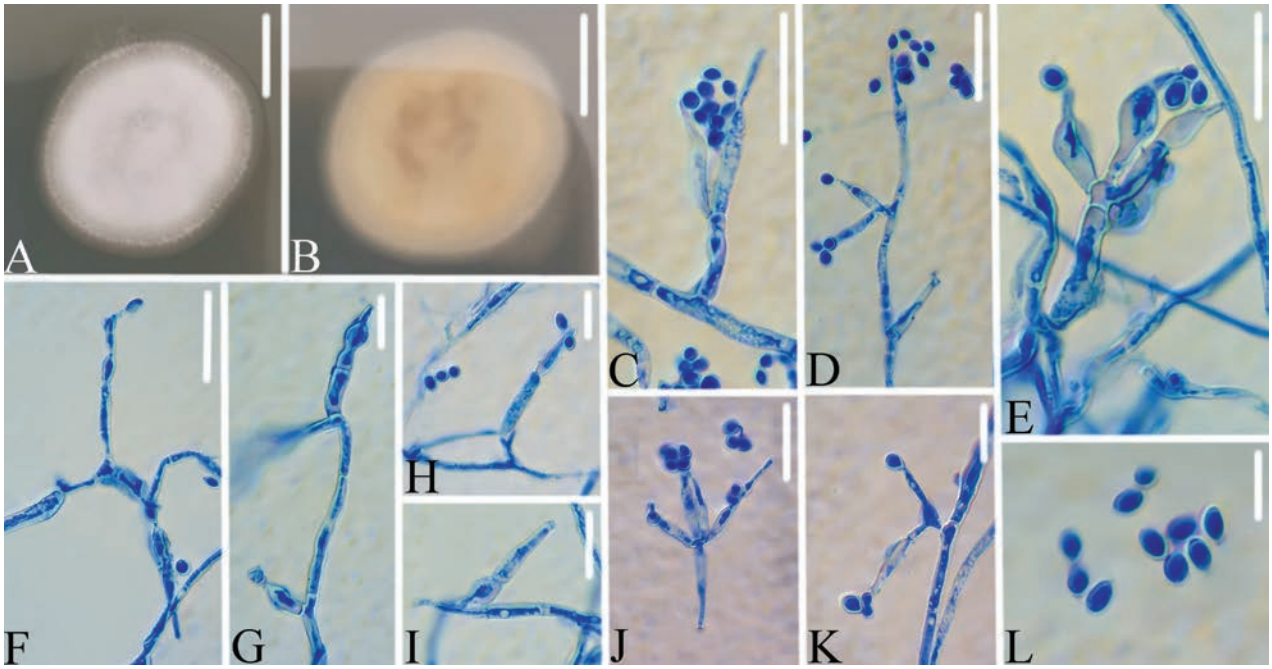

Figure 3. *Purpureocillium zongqii* **A**, **B** colony on PDA (**A** obverse, **B** reverse) **C–J** Phialides and conidia. Scale bars: 10 mm (**A**, **B**); 10 µm (**C–J**).

Notes. *Purpureocillium zongqii* was easily identified as *Purpureocillium*, based on the BLASTn result in NCBI. Phylogenetic analyses show that *P. zongqii* has a close relationship to *P. lilacinum* (Fig. 1). However, *P. zongqii* was easily distinguished from *P. lilacinum* (conidiophores: 4–6 × 3–4 µm; conidia: ellipsoidal to fusiform, 2–3 × 2–4 µm; phialide, 6–9 × 2.5–3 µm; purple colony) (Luangsa-ard et al. 2011) by its larger conidiophores, larger ellipsoidal conidia, larger phialide and white colony. Thus, the morphological characteristics and molecular phylogenetic results support *P. zongqii* as a new species.

Keys of the genus *Perennicordyceps*

1 Parasitic on fungi **2**
– Parasitic on insects **3**
2 Phialides 14.8–64.9 × 1.9–3.1 µm, conidia globose to ellipsoid ..... ***Perennicordyceps lutea***
– Phialides 12–16 × 0.6–1.5 µm, conidia fusiform to ellipsoid to inequilateral shaped ..... ***Perennicordyceps elaphomyceticola***
3 Typical host larva of cicada or moth **4**
– Typical host larva of beetle **5**
4 Typical host larva of cicada, conidia globose, fusiform 1.5–3.5 (2.5) × 1.1–1.8 (1.4) µm ..... ***Perennicordyceps prolifica***
– Typical host larva of moth, conidia ellipsoidal to cylindrical, 3.4–4.8 × 2.5–2.7 µm ..... ***Perennicordyceps zongqii***
5 Conidiophores quasi-verticillate branching **6**
– Conidiophores irregular branching ..... ***Perennicordyceps cuboidea***
6 Conidia ellipsoid, 2.5–3.9 (3.1) × 1.0–1.4 (1.2) µm, mainly *Acremonium*-like phialide ..... ***Perennicordyceps ryogamiensis***
– Conidia aubglobose, fusiform, 1.3–1.9 (1.8) × 1.0–1.9 (1.4) µm, mainly *Hirsutella*-like phialide ..... ***Perennicordyceps paracuboidea***

Keys of the genus *Purpureocillium*

1 Species that grow on spiders and insect forming synnemata of colours purple to lilac **2**
– Species isolated, clinical specimens on human, animals, soil and crystals salt **3**
2 Synnemata lilac coloured, conidia ellipsoid to cylindrical 4.8–5.6 × 1.6–2.4 µm; parasite trapdoor spiders; sexual state *Cordyceps cylindrica* ..... ***Purpureocillium atypicola***
– Synnemata lilac coloured, conidia ellipsoid 2.5–4 × 1.4–1.8 µm; parasite on cadavers of cicada adults; sexual state in *Cordyceps ryogamimontana* ..... ***Purpureocillium takamizusanense***
3 *Acremonium*-like synanamorph absent **4**
– *Acremonium*-like synanamorph present **5**
4 Phialides 8–10 (14) × 2–3 µm, conidia globose, 2–2.5 µm ..... ***Purpureocillium roseum***
– Phialides 6.8–11.7 × 2.6–4.0 µm, conidia ellipsoidal, 2.7–4.2 × 2.0–2.4 µm ..... ***Purpureocillium zongqii***

5 Conidia subglobose with apiculate base or limoniform **6**
– Conidia ellipsoidal to fusiform ..... ***Purpureocillium lilacinum***
6 Conidia 2–3 × 2–2.5 µm ..... ***Purpureocillium lavendulum***
– Conidia 3.5–5.5 × 3–4.5 µm ..... ***Purpureocillium sodanum***

Discussion

The genus *Perennicordyceps* was proposed to accommodate four species of *Polycephalomyces*, *Polycephalomyces prolificus* (Kobayasi) Kepler & Spatafora, *P. cuboideus* (Kobayasi & Shimizu) Kepler & Spatafora, *P. paracuboideus* (S. Ban, Sakane & Nakagiri) Kepler & Spatafora and *P. ryogamiensis* (Kobayasi & Shimizu) Kepler & Spatafora (Matočec et al. 2014). Species in the genus usually known as entomopathogenic fungi with host in the orders Coleoptera and Hemiptera (Matočec et al. 2014). Xiao et al. (2023) reported a new species, *Perennicordyceps lutea* Y.B. Wang, H. Yu & Y.P. Xiao and a new combined species, *P. elaphomyceticola* (W.Y. Chuang, H.A. Ariyaw., J.I. Yang & Stadler) Y.P. Xiao & K.D. Hyde, which were both recorded as fungicolous. In the present study, the new species *P. zongqii* with Lepidoptera larvae was introduced. *Cordyceps*-like fungi have evolved adaptively through nutrient exchange and the ultimate goal is in the search of ideal food (Moonjely et al. 2016; Vidhate et al. 2023). Whether the new species has coevolved with its hosts and has special metabolizing processes is worthy of further research.

The genus *Purpureocillium* was established to accommodate *Paecilomyces lilacinus* Thom (Luangsa-ard et al. 2011). Members of *Purpureocillium* have a global distribution, especially for the type species *P. lilacinum*, which is commonly isolated from soil, decaying vegetation, insects, nematodes and laboratory air (as contaminant) (Luangsa-ard et al. 2011; Perdomo et al. 2013; Quandt et al. 2014; Ban et al. 2015b; Calvillo-Medina et al. 2021). In the present study, the new species *P. zongqii* was isolated from soil in Monkey-Ear Tiankeng. Tiankeng acts as a refugium for biodiversity amid changing global climate and some ancient (*Alsophila spinulosa* (Wall. ex Hook.) R. M. Tryon) and unique plants (cool-adapted plants) were present in Tiankeng (Shui et al. 2015; Bátori et al. 2017; Pu et al. 2019; Shen et al. 2020). Whether the new species is more ancient than others, has coevolved with its environment and has special metabolizing processes is worthy of further research.

The karst region in southwestern China is one of the 36 biodiversity hotspots in the world, nurturing a large number of endemic species (Delgado Baquerizo et al. 2020), especially in the special eco-environment, Tiankeng and the valley. The species that exist in these habitats often have very narrow distribution areas and very small populations, and urgently need to be protected (Wu and Zhang 2020). In the present study, species in the families Polycephalomycetaceae and Ophiocordycipitaceae were introduced in Tiankeng and the valley for the first time. Further attention needs to be paid to the diversity of other *Cordyceps*-like fungi in the special eco-environment of karst region.

Abstract

The lichenised fungal genus *Pyrenula* is a very common crustose lichen element in tropical to subtropical forests, but little research has been done on this genus in China. We carried out an integrative taxonomic study on *Pyrenula* in China using morphological, anatomical, chemical characters, and molecular data (ITS, nuLSU, mtSSU). Three new species with muriform ascospores containing red oil when over-mature were found: *Pyrenula submacularis* **sp. nov.**, *P. yunguiensis* **sp. nov.** and *P. rufotetraspora* **sp. nov.** Molecular data and TLC results of *P. macularis* and *P. breutelii* are for the first time reported and show that they are not synonyms. This is the first report of *P. breutelii* in China. Contrary to the previous reports of this genus, we found lichen substances in all the five species in this study, seemingly terpenoids. A key for the *Pyrenula* species reported in China is provided.

Key words: Chemical substances, diversity, morphology, new taxa, phylogeny

Introduction

The lichen genus *Pyrenula* Ach. (Pyrenulaceae) was first established by Acharius, with *Pyrenula nitida* (Weigel) Ach. as the type species (Acharius 1814). *Pyrenula* grows on bark mainly in tropical and subtropical forests (Aptroot 2012; Mendonça et al. 2016). The genus is characterised by perithecioid ascomata, with or without pseudocyphellae, with or without lichexanthone or anthraquinones, with distoseptate, transversely septate or (sub)muriform ascospores. UV-reaction of thallus, presence of hamathecium inspersion and the shape of the ascospore lumina (especially whether there is an endospore between the end lumina and the wall) are also important characters (Aptroot 2012; Mendonça et al. 2016).

Based on integrative taxonomic studies applying molecular, morphological, anatomical, and chemical characters, including the long-overlooked characters inspersion and iodine reaction of the hamathecium, we reported three new species of *Pyrenula* (*P. inspersa*, *P. thailandicoides* and *P. apiculata*), which have 3-septate ascospores with red or orange oil when over-mature (Dou et al. 2024). The presence of red or orange oily granules, which occur in over-mature ascospores

of some *Pyrenula* species, was first recognised by Harris (Harris 1989). He pointed out the significance of the degradation stage of spores for the taxonomy of *Pyrenula*. Aptroot et al. described the degradation process in detail: in a few species, the old spores assume a reddish tinge, the wall becomes red-brown and the remains of the lumina develop into red or orange granules (Aptroot et al. 2013). Now, a total of eleven species with red or orange oil in over-mature ascospores are known, of which seven have transversely distoseptate ascospores, viz. *P. concastroma* R.C. Harris, *P. bahiana* Malme, *P. sexlocularis* (Nyl.) Müll. Arg., *P. thailandica* Aptroot, *P. inspersa* M.Z. Dou & Z.F. Jia, *P. thailandicoides* M.Z. Dou & Z.F. Jia and *P. apiculata* M.Z. Dou & Z.F. Jia; four have (sub)muriform ascospores, viz. *P. endocrocea* Aptroot, *P. seminuda* (Müll. Arg.) Sipman & Aptroot, *P. breutelii* (Müll. Arg.) Aptroot and *P. macularis* (Zahlbr.) R.C. Harris.

In the world key of *Pyrenula* species, Aptroot accepted 169 species out of the ca. 745 named taxa in the genus (Aptroot 2012). Since then, many new species of *Pyrenula* have been described and the genus now comprises ca. 245 species (Aptroot 2012, 2021; Aptroot et al. 2012, 2013, 2018; Mendonça et al. 2016; Ingle et al. 2018; Miranda-González et al. 2022; Mishra et al. 2022; Soto-Medina et al. 2023; Lücking et al. 2023; Sipman, 2023; Dou et al. 2024), of which 46 species have so far been found in China (Aptroot and Seaward 1999; Aptroot 2003; Fu et al. 2018, 2019; Wang et al. 2018; Wei 2020; Xie et al. 2021; Dou et al. 2024; Li et al. 2024).

Here, we add three new species of *Pyrenula* with muriform ascospores with red oil when over-mature. In addition, we found that *P. macularis* is not synonymous with *P. breutelii* (Aptroot 2012). These classification results are strongly supported by molecular phylogeny. Few species of *Pyrenula* have been established based on phylogenetic result previously.

Materials and methods

Morphological and chemical analyses

The specimens were collected in the provinces Hunan, Fujian, Guizhou and Guangdong of China and are preserved in the Fungarium of the College of Life Sciences, Liaocheng University, China (LCUF). Morphological characters of thalli and apothecia were examined in the usual way and photographed under an Olympus SZX16 dissecting microscope with an Axio Imager. The anatomical characters were observed and measured under an Olympus BX53 compound microscope with an Olympus DP74 Imager. The lichen secondary metabolites were studied by thin-layer chromatography using solvent C (Orange et al. 2010).

DNA extraction, PCR sequencing and phylogenetic analysis

The genomic DNA of ascomata was extracted using the Hi-DNA-secure Plant Kit (Tiangen, Beijing, China) according to the manufacturer's protocol. The mtSSU, ITS and nuLSU regions were amplified using the primer pair mrSSU1/3R (Zoller et al. 1999), ITS1F/ITS4 (White et al. 1990; Gardes and Bruns 1993) and AL2R/LR6 (Vilgalys and Hester 1990; Mangold et al. 2008). PCR reactions were carried out in 25 µL reaction system containing 1 µL each primer solution (10 µM), 0.5 µL genomic DNA, 10 µL ddH2O, and 12.5 µL 2×Taq PCR MasterMix®. Thermocycling conditions for mtSSU comprised initial denaturation at 94 °C (3 min);

35 denaturation cycles at 94 °C (30 s), annealing at 52 °C (30 s), extension at 72 °C (1.5 min), and a final extension at 72 °C for 10 min. The PCR amplification progress for nuLSU followed Dou et al. (Dou et al. 2018). Thermocycling conditions for ITS comprised initial denaturation at 94 °C (3 min); 35 denaturation cycles at 94 °C (30 s), annealing at 52 °C (30 s), extension at 72 °C (1.5 min), and a final extension at 72 °C for 10 min. The target products of PCR were affirmed by electrophoresis on 1% agarose gels and sequenced by TsingkeBiotechnology Co.,Ltd. (Tsingtao). The newly-generated sequences were submitted to GenBank (https://www.ncbi.nlm.nih.gov/, accessed on 31 December 2025; Table 1).

The sequences of mtSSU, ITS and nuLSU were combined, and the alignment included 118 ITS sequences, 94 LSU sequences and 76 SSU sequences, representing 127 taxa. The sequences of 5 taxa were newly generated (Table 1) and the sequences of 122 taxa were downloaded in GenBank (Suppl. material 1) (Lutzoni et al. 2001; Geiser et al. 2006; Weerakoon et al. 2012; Gueidan et al. 2016). *Endocarpon pusillum* and *Cyphellophora europaea* were chosen as outgroup, based on previous studies (Gueidan et al. 2016). All *Pyrenula* taxa that could be found in GenBank were included in our data matrix.

The alignment of sequences for each marker (mtSSU, ITS and nuLSU) was undertaken independently by applying MAFFT 7 (Katoh and Standley 2013). We used the "maskSegment" function in the R package AlignmentFilter (Zhang et al. 2023) to mask ambiguously-aligned or overly-divergent segments (stringency-controlling parameter prob set to 0.05) and then used the "degap" function to remove sites with more than 50% gaps. The congruence of the two datasets was tested using a 70% reciprocal bootstrap criterion (Mason-Gamer and Kellogg 1996): the three matrices (mtSSU, ITS and nuLSU) were analysed separately with RaxML v.8.2.12 (Stamatakis 2014) using 100 bootstrap pseudoreplicates and implementing a GTRGAMMA model on the CIPRES Web Portal (http://www.phylo.org). The resulting trees were compared and any hard conflicts detected were eliminated by pruning sequences or taxa out of the datasets. The three single-locus alignments were concatenated in PhyloSuite v.1.2.2 (Zhang et al. 2020). The concatenated data matrix comprised 2440 characters (726 for mtSSU, 730 for ITS and 984 fornuLSU). For BI (Bayesian Inference) analysis, PartitionFinder 2 (Lanfear et al. 2017) was used to determine the best-fit model for each partition. The dataset was partitioned into gene groups, with the

Table 1. Information for the sequences used in this study. Newly generated sequences are shown in bold.

GTR+I+G, SYM+I+G and GTR+I+G substitution models applied to mtSSU gene, ITS gene and nuLSU gene, respectively. BI analysis was performed with MrBayes 3.2.7 (Ronquist et al. 2012). Two runs of four chains were carried out for 10,000,000 generations and trees were sampled every 1000 generations. The first 25% of the convergence runs were discarded as burn-in. Construction of the ML (Maximum Likelihood) tree was undertaken by applying RAxML v.8.2.12 (Stamatakis 2014), using 100 bootstrap pseudoreplicates and a GTRGAMMA model on the CIPRES Web Portal (http://www.phylo.org). ML bootstrap values (BS) ≥ 70% and Bayesian posterior probabilities (PP) ≥ 0.95 were considered as significantly supported. The alignments were deposited in TreeBase (http://purl.org/phylo/treebase/phylows/study/TB2:S31341).

Results

Phylogenetic analyses

The dataset includes 118 ITS sequences, 76 mtSSU sequences and 94 nuLSU sequences, of which 11 ITS sequences, 2 mtSSU sequences, and 9 LSU sequences are newly generated in this study. The BI and ML (Suppl. material 2) trees showed similar topologies, so only the BI tree is provided here as Fig. 1. Compared with the dataset of Gueidan et al. (2016), our phylogenetic analysis includes eleven additional species (the three new species, *Pyrenula macularis*, *P. breutelii*, *P. sanguinea*, *P. nitidella*, *P. cf. acutalis*, *P. punctella*, *P. cf. leucostoma* and *P. occidentalis*). Our phylogenetic result confirms the presence of two main well-supported monophyletic groups coinciding with the presence/absence of pseudocyphellae as shown in Weerakoon et al. (2012) and Gueidan et al. (2016). Our phylogenetic results also confirm the delimitation problems of several taxa, for example, *P. quassiicola*, *P. mamillana* and *P. rubrostigma*, which is consistent with Gueidan et al. (2016).

The phylogenetic tree revealed five monophyletic lineages corresponding to five different species: *Pyrenula submacularis* M.Z. Dou & Z.F. Jia, sp. nov., *P. yunguiensis* M.Z. Dou & Z.F. Jia, sp. nov., *P. rufotetraspora* M.Z. Dou & Z.F. Jia, sp. nov., *P. macularis* (Zahlbr.) R.C. Harris and *P. breutelii* (Müll. Arg.) Aptroot. The clades of the five species were all strongly supported. The support values [posterior probability (PP)/bootstrap value (BS)] of the two specimens of *P. submacularis* was 1/100, the three specimens of *P. yunguiensis* 0.99/98, the two specimens of *P. breutelii* 0.96/83, the three specimens of *P. macularis* 1/100. Although *P. rufotetraspora* clustered with *P. submacularis* with high support (1/92), *P. yunguiensis* clustered with *P. pyrenuloides* (0.99/-), and *P. breutelii* clustered with *P. thelomorpha* (1/100), they can be distinguished easily in anatomical characters. *P. macularis* and *P. breutelii* are far apart on the phylogenetic tree. These five species all belong to Group 1.

Chemistry

Before the report (Dou et al. 2024), TLC results had not been described in detail in the literature of *Pyrenula*. They were either not mentioned or interpreted as nothing detected. However, our TLC results show several spots, indicating that there are multiple lichen substances in species of *Pyrenula* (Suppl. materials 3, 4). The weak visibility in short-wave UV (plate A) and the reddish color after charring (plate B) suggest that most spots concern terpenoids.

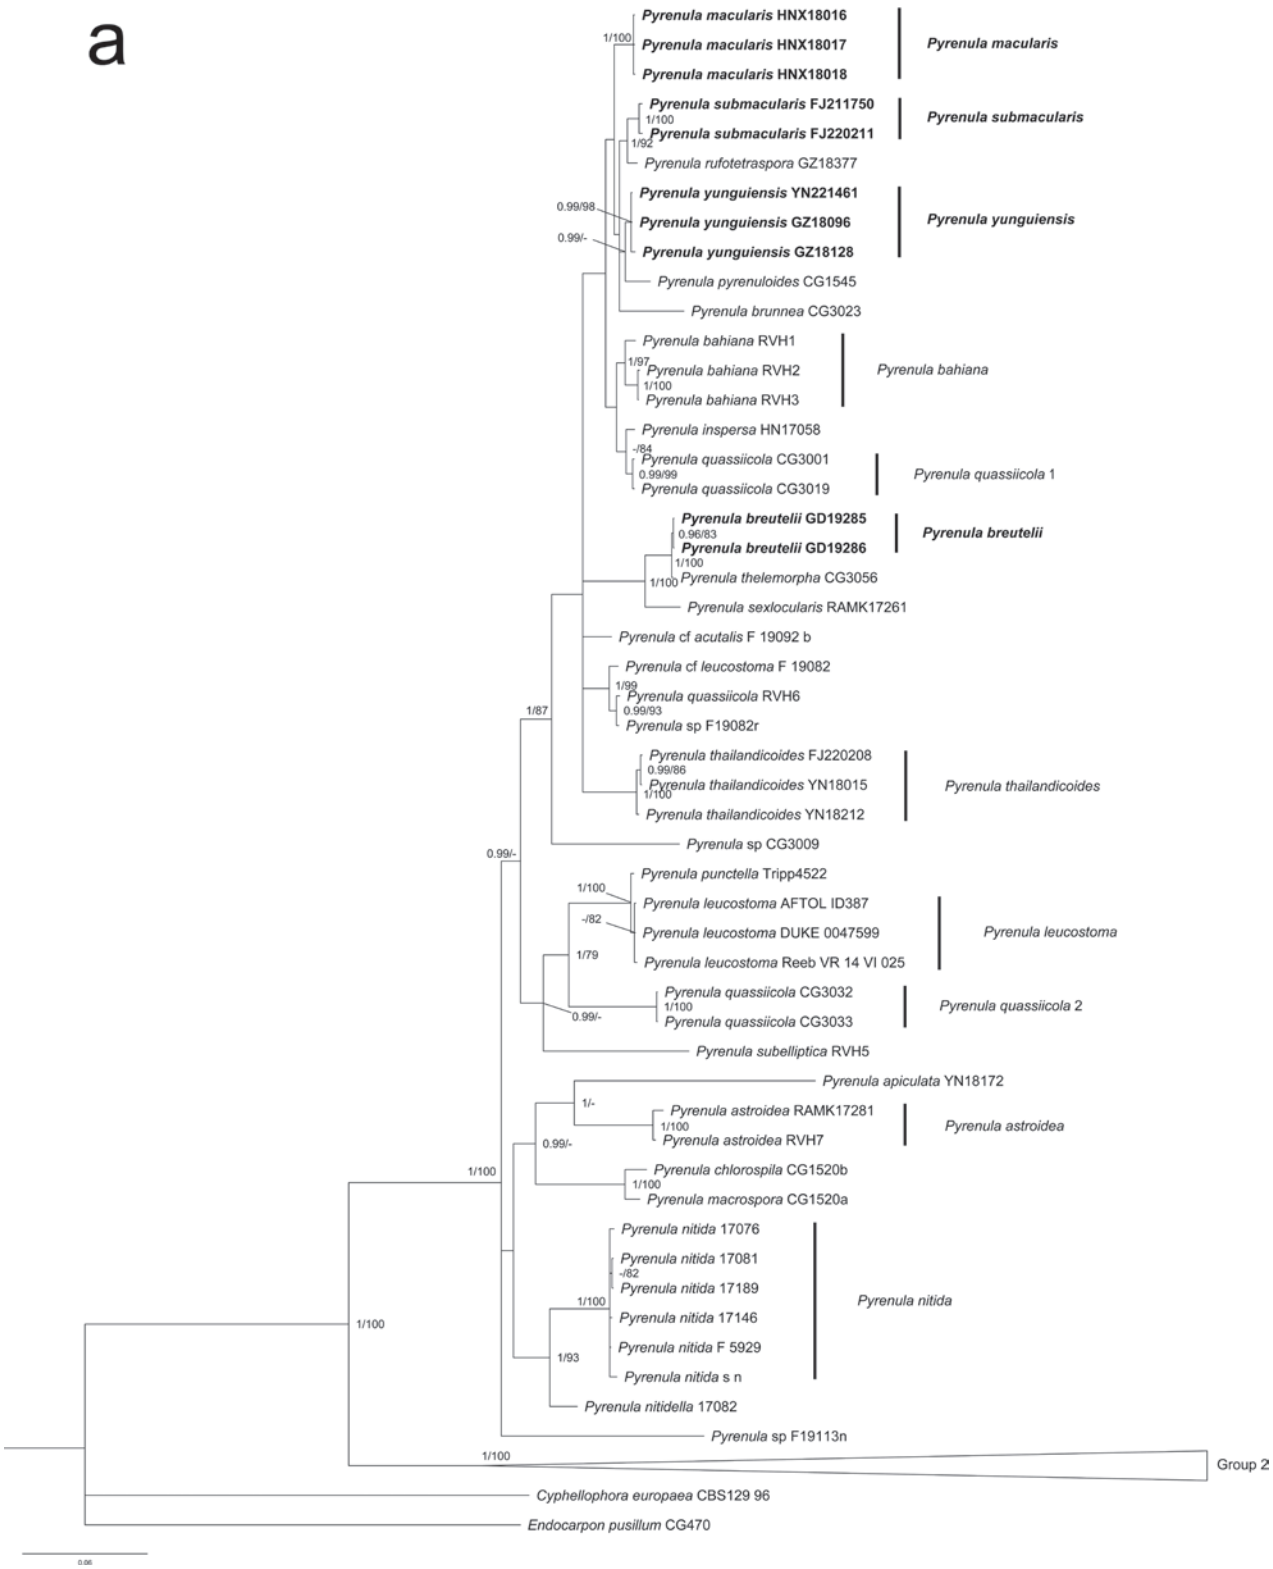

Figure 1. Phylogeny of the genus *Pyrenula* based on a three-gene dataset (mtSSU, ITS and nuLSU) **a** overview of the entire tree and details of Group 1 **b** details of Group 2. Most likely tree obtained using MrBayes. Support values are reported above the branches [posterior probability (PP)/bootstrap value (BS)]. Only significant values (higher than 95% PP and higher than 70% BS) are shown. *Cyphellophora europaea* and *Endocarpon pusillum* are the out-group taxa.

Figure 1. Continued.

Additional solvents and an experienced chemist will be needed to identify them further. On plate C the terpenoid spots are more intensely colored. A comparison between the *Pyrenula* species represented on the plate C suggests that all have the same series of red color that are green under daylight on the plate B. Reddish spots with yellow rim in class 7 in Suppl. material 3 are probably terpenoids from treebark; they are strongest in samples without lichen. In some samples some of the spots are different from those of the other species.

The TLC experiments of less closely related species were also carried out (Suppl. materials 5, 6). The species in Suppl. materials 5, 6 belong to ten genera (*Pyrenula*, *Phyllobaeis*, *Coenogonium*, *Ocellularia*, *Allographa*, *Graphis*, *Platythecium*, *Phyrrospora*, *Malmidea*, *Thelotrema*) and eight families (Pyrenulaceae, Baeomycetaceae, Coenogoniaceae, Diploschistaceae, Graphidaceae, Lecanoraceae, Malmideaceae, Thelotremataceae). The *Pyrenula* sp. in Suppl. material 5 is a record in China not yet published and included in the Group 2 of phylogenetic tree. This *Pyrenula* species did not produce the chemical substances that were red after charring under 365 nm ultraviolet light and green under daylight. The two white spots of this *Pyrenula* species at Rf 2 on the plate C in Suppl. material 5 might represent the same chemical substances as the two white spots of *P. macularis* (no. nr. 5 and 6) on the plate C in Suppl. material 4. Although the species of *Allographa* (no. nr. 2, 7, 11, 12, 13 of Suppl. material 5) showed red spots after charring under 365 nm ultraviolet light at Rf 5, the spots were yellow under daylight, not green. None of the other species in Suppl. materials 5, 6 produces the same chemical substance as the five species of *Pyrenula* reported here. Given that phylogenetic approach and that chemical characters are underestimated and limited to few specimens and areas, we predict that our findings only represent the tip of the iceberg in this genus.

Taxonomy

Pyrenula submacularis **M.Z. Dou & Z.F. Jia, sp. nov.**
MycoBank No: 853430
Fig. 2

Etymology. The specific epithet submacularis refers to the similarity to *Pyrenula macularis*.

Holotype. China • Fujian Province, Wuyi Mountain, Tongmu Village Reserve, Wuyi Mountain National Park, Science and Technology Building, 27°44'31"N, 117°40'44"E, alt. 700 m, on bark, 24 October 2021, Y.F. Zhao (LCUF FJ211750, holotype; GenBank PP692372 for ITS, and PP692480 for nuLSU).

Diagnosis. The new species can be distinguished from the most similar species *Pyrenula macularis* Aptroot by bigger ascospores with more locules and different lichen substances.

Description. Thallus corticolous, crustose, olive-green in the field and khaki after drying, surface dull, corticate with pseudocyphellae, UV-. Apothecia emergent, dispersed, low conical, 1.0–2.0 mm diam., the sides often partly covered by the thallus, with crystals, wall completely carbonized when mature and even falls apart. Ostioles apical, white. Hamathecium not inspersed, IKI+ blue and occasionally red. Ascospores 8 per ascus, uniseriate or subbiseriate, elliptical, with rounded ends, 40–65 × 16–21(–28) µm, hyaline to brown, muriform, with c. 7–9 × 2–7 locules, lumina rounded, old spores containing globules of red oily substance.

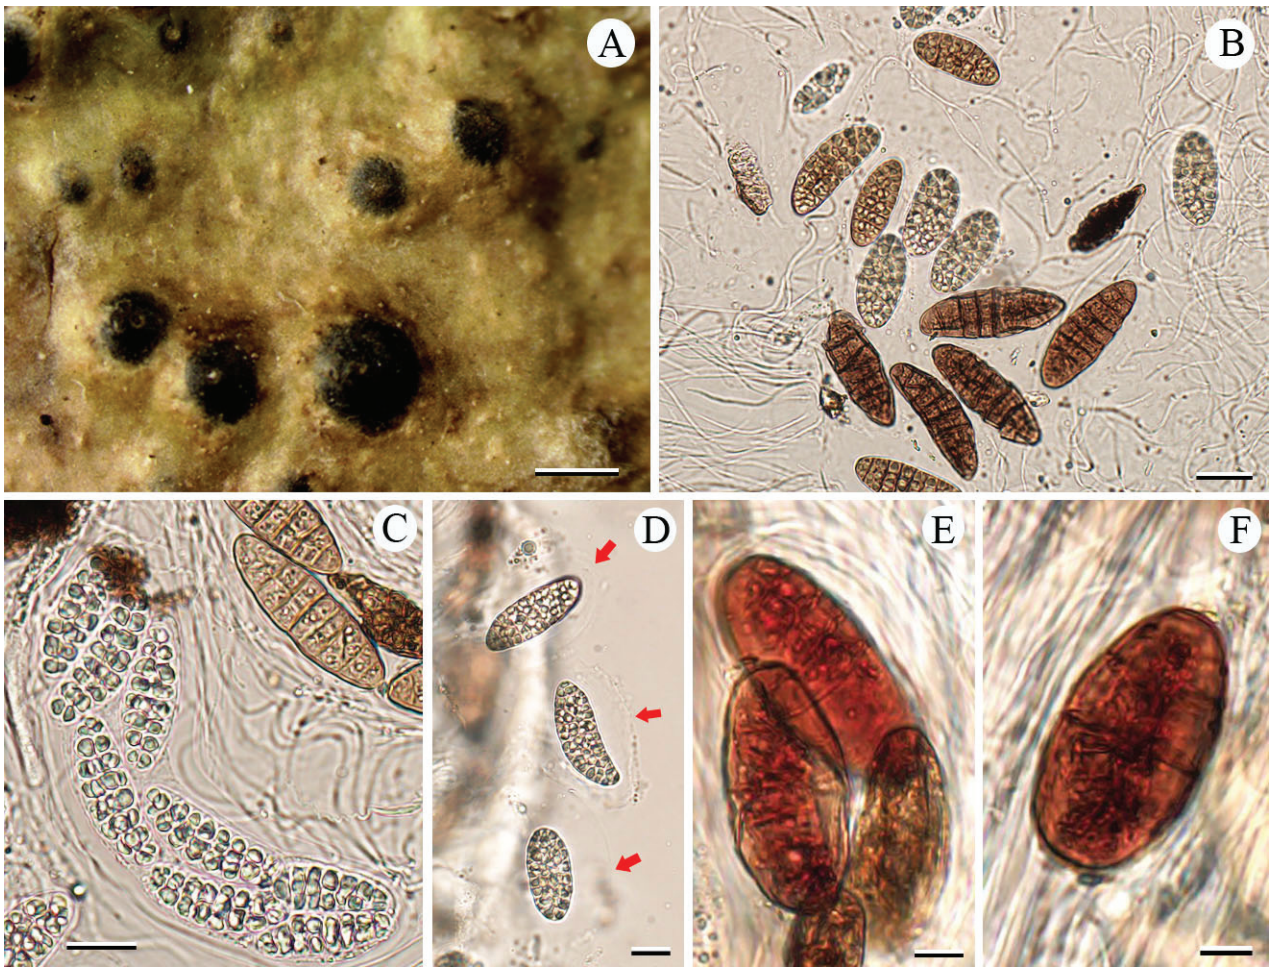

Figure 2. *Pyrenula submacularis* sp. nov. (holotype, LCUF FJ211750) **A** thallus with ascomata and pseudocyphellae **B** ascospores at different developmental stages **C** ascus, with 8 ascospores **D** red arrows show gelatinous halo **E, F** over-mature ascospores with orange-oil. Scale bars: 1 mm (**A**); 30 µm (**B**); 20 µm (**C, D**); 10 µm (**E, F**).

Chemistry. Thallus UV-. TLC with solvent C showed unidentified black spots at Rf two, three, four, five and six under 254 nm ultraviolet light; unidentified green spot at Rf four and brick red spots at Rf five after charring under daylight; unidentified red spots at Rf three and four, and one unidentified fluorescent spot at Rf five after charring under 365 nm ultraviolet light (Suppl. material 3).

Habitat and distribution. The new species is currently only known from the subtropical regions of southern China on bark.

Additional specimens examined. China • Fujian Province, Longyan City, Dongxiao National Forest Park, Frog Stone, 24°58'07"N, 117°01'14"E, alt. 679 m, on bark, 12 July 2022, Z.G. Ma (LCUF FJ220211; GenBank PP692377 for ITS, and PP692481 for nuLSU).

Notes. This new species is similar to *Pyrenula seminuda*, *P. endocrocea*, *P. breutelii* and *P. macularis* in having (sub)muriform ascospores with red or orange oil when over-mature. This new species differs from *P. seminuda* by bigger and muriform ascospores with more locules, the latter 22–40 × 10–17 µm and submuriform with 6 × 1–2 locules, most transverse locules being single and few with an oblique or longitudinal division (Aptroot et al. 2013). *P. endocrocea* differs from this new species by medulla with a soft layer of copious orange

anthraquinone crystals reacting UV+ red and KOH+ crimson, and smaller ascospores, (30–)32–44(–50) × 13–16(–19) µm (Aptroot et al. 2012). This new species (*P. submacularis*) differs from *P. breutelii* in lichen substances (Suppl. material 3) and by bigger ascospores and more locules, the latter 25–35 × 12–13 µm and 8 × 3–4 locules (Müller 1885). *P. submacularis* (no. nr. 5 and nr. 6 in Suppl. material 3) has two more black spots at Rf two and three under 254 nm ultraviolet light than *P. breutelii* (no. nr. 15 and nr. 16 in Suppl. material 3). And the new species has one more spot with fluorescence at Rf five after charring under 365 nm ultraviolet light than *P. breutelii* (Suppl. materials 3, 4). This new species (*P. submacularis*) can be distinguished from the most similar species *P. macularis* by different lichen substances and bigger ascospores and more locules, the latter 34–45 × 14–16 µm and 8 × 1–3 locules (Zahlbruckner 1930). *P. macularis* (no. nr. 5 and nr. 6 in Suppl. material 4) has two more black spots at Rf two under 254 nm ultraviolet light than *P. submacularis* (no. nr. 8 and nr. 10 in Suppl. material 4). And the new species has one more spot with fluorescence at Rf five after charring under 365 nm ultraviolet light than *P. macularis* (Suppl. materials 3, 4).

Pyrenula yunguiensis **M.Z. Dou & Z.F. Jia, sp. nov.**
MycoBank No: 853431
Fig. 3

Etymology. The specific epithet yunguiensis refers to the place where the specimen was collected.

Holotype. China • Guizhou Province, Duyun City, Doupeng Mountain Reserve, Mayao River Street, 26°22'32"N, 107°22'11"E, alt. 1107 m, on bark, 17 March 2018, F.Y. Liu (LCUF GZ18096, holotype; GenBank PP692374 for ITS, and PP692478 for nuLSU).

Diagnosis. The new species can be distinguished from the most similar species *P. submacularis* by bigger ascospores and different lichen substances.

Description. Thallus corticolous, crustose, olive-green in the field and khaki after drying, surface dull, corticate with pseudocyphellae, UV-. Apothecia emergent, dispersed, low conical, 0.5–2.0 mm diam., the sides often partly covered by the thallus, with crystals. Excipulum carbonized when mature and falls apart when over-mature. Ostioles apical, white. Hamathecium not inspersed, IKI+ red and occasional blue, the colour relating to development stage. Ascospores 8 per ascus, uniseriate, fusiform, with pointed or blunt ends, 50–70(–80) × 17–22(–26) µm, hyaline to brown, muriform, with c. 8 × 2–4 locules, lumina rounded, old spores containing globules of red oily substance.

Chemistry. Thallus UV-. TLC with solvent C showed unidentified black spots at Rf four and six under 254 nm ultraviolet light; unidentified green spot at Rf four on charred plate under daylight; unidentified red spots at Rf three, four and five on charred plate under 365 nm ultraviolet light (Suppl. material 3).

Habitat and distribution. The new species is currently only known from the subtropical regions of southern China on bark.

Additional specimens examined. China • Guizhou Province, Duyun City, Doupeng Mountain Reserve, Old Post Street, 26°22'35"N, 107°21'52"E, alt.

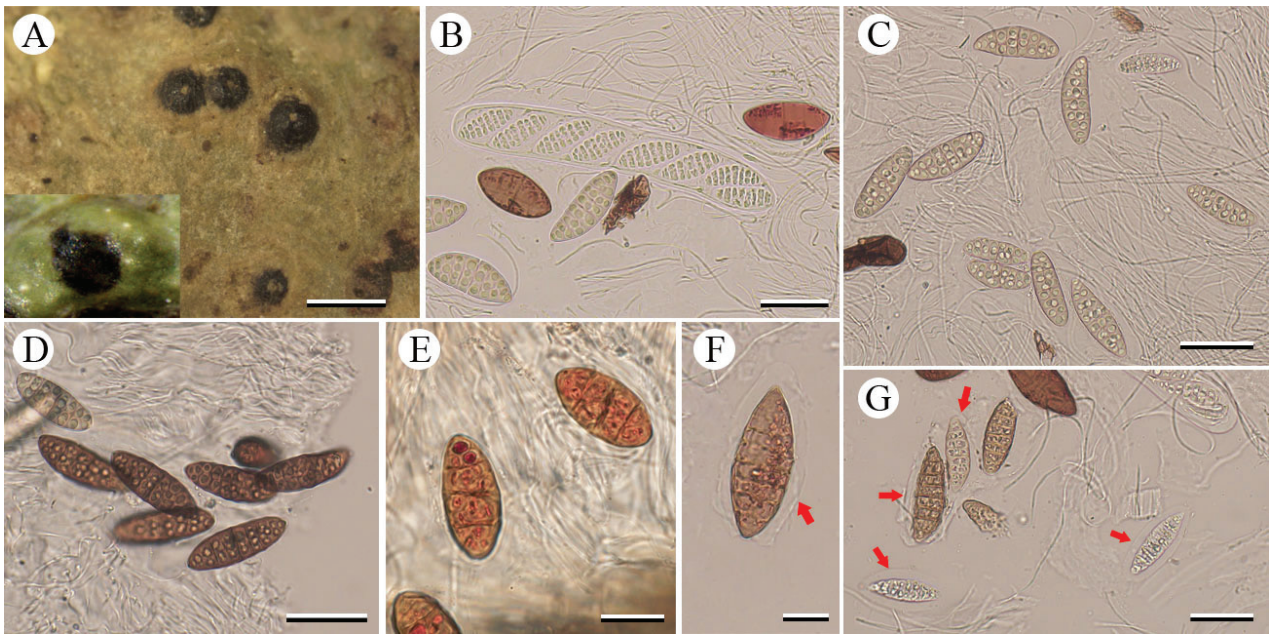

Figure 3. *Pyrenula yunguiensis* sp. nov. (holotype, LCUF GZ18096) **A** thallus with ascomata and pseudocyphellae **B** ascus, with 8 ascospores **C–G** ascospores at different developmental stages **E, F** over-mature ascospores with red-oil **F, G** red arrows show gelatinous halo. Scale bars: 1 mm (**A**); 50 µm (**B–D**); 20 µm (**E, F**); 40 µm (**G**).

1154 m, on bark, 17 March 2018, X.H. Wu (LCUF GZ18128; GenBank PP692373 for ITS and PP692479 for nuLSU). China • Yunnan Province, Jingdong County, Taizhong Town, Aishanting, 24°32'11"N, 101°01'53"E, alt. 2625 m, on bark, 16 August 2022, T. Jia (LCUF YN221461; GenBank PP692378 for ITS, and PP692477 for nuLSU).

Notes. This new species is similar to *Pyrenula seminuda*, *P. endocrocea*, *P. breutelii*, *P. macularis* and *P. submacularis* in having (sub)muriform ascospores with red or orange oil when over-mature. This new species differs from *P. seminuda* by bigger and muriform ascospores with more locules, the latter 22–40 × 10–17 µm and submuriform with 6 × 1–2 locules, most transverse locules being single and few with an oblique or longitudinal division (Aptroot et al. 2013). *P. endocrocea* differs from this new species by medulla with a soft layer of copious orange anthraquinone crystals reacting UV+ red and KOH+ crimson, and smaller ascospores, (30–)32–44(–50) × 13–16(–19) µm (Aptroot et al. 2012). This new species differs from *P. breutelii* by bigger ascospores, the latter 25–35 × 12–13 µm (Müller 1885). This new species can be distinguished from *P. macularis* by bigger ascospores, the latter 34–45 × 14–16 µm and 8 × 1–3 locules (Zahlbruckner 1930). This new species can be distinguished from the most similar species *P. submacularis* by different lichen substances, bigger ascospores and less locules, the latter 40–65 × 16–21(–28) µm and 7–9 × 2–7 locules. *P. submacularis* (no. nr. 5 and nr. 6 in Suppl. material 3; no. nr. 8 and nr. 10 in Suppl. material 4) has one more spot with fluorescence at Rf five after charring under 365 nm ultraviolet light than *P. yunguiensis* (no. nr. 8 and nr. 11 in Suppl. material 3; no. nr. 12 and nr. 14 in Suppl. material 4). Although *P. yunguiensis* clustered with *P. pyrenuloides* with high support (0.99/-), they can be distinguished easily in anatomical characters. *P. pyrenuloides* has no red or orange oil in over-mature ascospores and more locules (8–10 rows of up to ca. 10 each) (Harris 1989).

***Pyrenula rufotetraspora* M.Z. Dou & Z.F. Jia, sp. nov.**
MycoBank No: 853432
Fig. 4

Etymology. The specific epithet rufo refers to the red oil in over-mature ascospores and tetraspora means that there are four spores in each ascus.

Holotype. China • Guizhou Province, Libo County, Xiaoqikong Scenic Area, Laya Waterfall, 25°15'10"N, 107°44'06"E, alt. 425 m, on bark, 24 October 2018, Z.F. Jia (LCUF GZ18377, holotype; GenBank PP692371 for ITS, and PP692474 for nuLSU).

Diagnosis. This new species can be distinguished from the most similar species *Pyrenula yunguiensis* by fewer ascospores per ascus, bigger ascospores, more locules and different lichen substances.

Description. Thallus corticolous, crustose, olive-green in the field and khaki after drying, surface dull, corticate with pseudocyphellae, UV-. Apothecia emergent, dispersed, conical, 0.6–1.2 mm diam., the sides often partly covered by the thallus, with crystals. Excipulum completely carbonized when mature and falls apart when over-mature. Ostioles apical, white or brown. Hamathecium not inspersed, IKI+ red. Ascospores 4 per ascus, uniseriate, fusiform, with pointed or blunt ends, 70–100(–106) × (17–)21–27(–41) µm, hyaline to brown, muriform, with c. 10–12 × 3–14 locules, lumina rounded, old spores containing globules of red oily substance.

Chemistry. Thallus UV-. TLC with solvent C showed one unidentified black spot at the dividing line of Rf three and four under 254 nm ultraviolet light; unidentified red substances at Rf four under 365 nm ultraviolet light (Suppl. material 3).

Habitat and distribution. The new species is currently only known from the subtropical regions of southern China on bark.

Notes. This new species is similar to *Pyrenula seminuda*, *P. endocrocea*, *P. breutelii*, *P. macularis*, *P. submacularis* and *P. yunguiensis* in having (sub) muriform ascospores with red or orange oil when over-mature. This new species differs from *P. seminuda* by bigger and muriform ascospores with more locules, the latter 22–40 × 10–17 µm and submuriform with 6 × 1–2 locules, most transverse locules being single and few with an oblique or longitudinal division (Aptroot et al. 2013). *P. endocrocea* differs from this new species by medulla with a soft layer of copious orange anthraquinone crystals reacting UV+ red and KOH+ crimson, and smaller ascospores, (30–)32–44(–50) × 13–16(–19) µm (Aptroot et al. 2012). This new species can be distinguished from *P. breutelii*, *P. macularis*, *P. submacularis* and *P. yunguiensis* by different lichen substances (Suppl. materials 3, 4), bigger ascospores, more locules and fewer ascospores per ascus. There are 8 ascospores in per ascus in *P. breutelii*, *P. macularis*, *P. submacularis* and *P. yunguiensis*, 4 in the new species. *P. rufotetraspora* showed a black spot at the dividing line of Rf three and four under 254 nm ultraviolet light (no. nr. 13 on Suppl. material 3), which was not red on charred plate under 365 nm ultraviolet light. This black spot did not exist in *P. breutelii*, *P. macularis*, *P. submacularis* and *P. yunguiensis* and located at Rf four under 254 nm ultraviolet light on Suppl. material 4 (no. nr. 16). The difference of locations of this spot on Suppl. materials 3, 4 might be caused by edge effect. *P. submacularis* is sister to *P. rufotetraspora* with high support (1/92), but the latter has fewer ascospores in ascus (4) and obviously bigger ascospores.

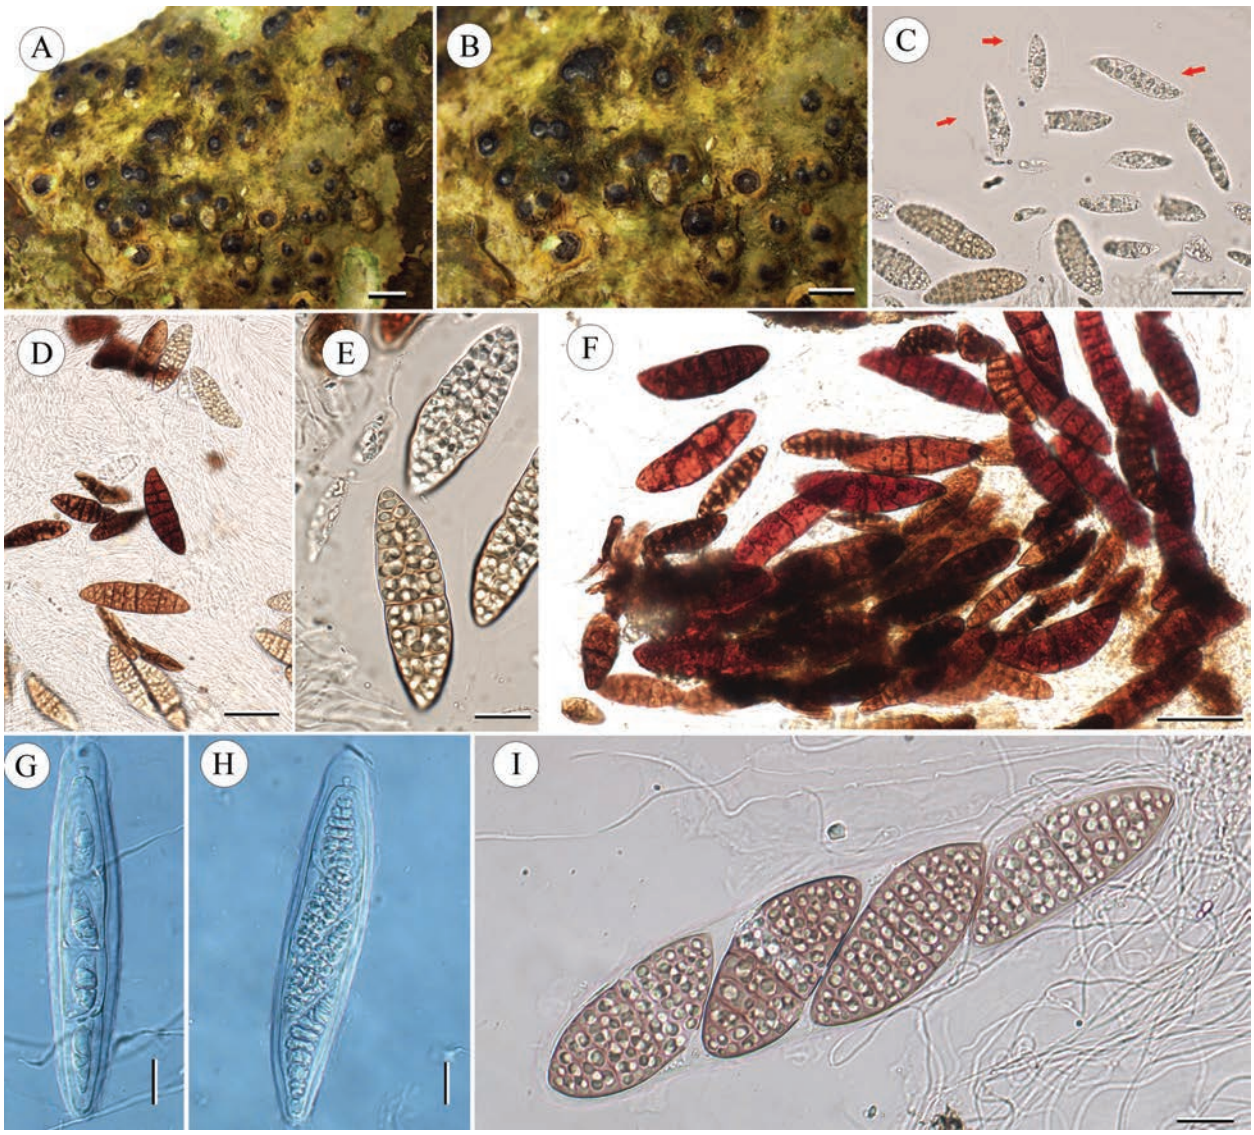

Figure 4. *Pyrenula rufotetraspora* sp. nov. (holotype, LCUF GZ18377) **A, B** thallus with ascomata **C–F** ascospores at different developmental stages, red arrows in **C** show gelatinous halo around immature ascospores **G–I** ascus, with 4 ascospores. Scale bars: 2 mm (**A, B**); 50 µm (**C, D**); 20 µm (**E**); 50 µm (**F**); 20 µm (**G, H**); 25 µm (**I**).

***Pyrenula breutelii* (Müll. Arg.) Aptroot**
MycoBank No: 563102
Fig. 5

Basionym. *Anthracothecium breutelii* Müll. Arg., *Flora* 68: 339 (1885).

Holotype. St Thomas, *Breutel*, ex hb. Hampe 1877 (G).

Description. Thallus corticolous, crustose, olive-green in the field and khaki after drying, surface dull, corticate with abundant pseudocyphellae, UV-. Apothecia perithecioid, dispersed, aggregated occasionally when crowded, low conical, 0.3–0.5 mm diam., the sides often partly covered by the thallus, with crystals. Excipulum carbonized when mature and falls apart when over-mature. Ostioles apical, white. Hamathecium not inspersed, IKI+ red. Ascospores 8 per ascus, subbiseriate, fusiform, with pointed or blunt ends, (23–)25–37(–41) × (10–)12–15(–18) µm, hyaline to brown, muriform, with c. 8 × 1–4 locules, lumina rounded, old spores containing globules of red oily substance.

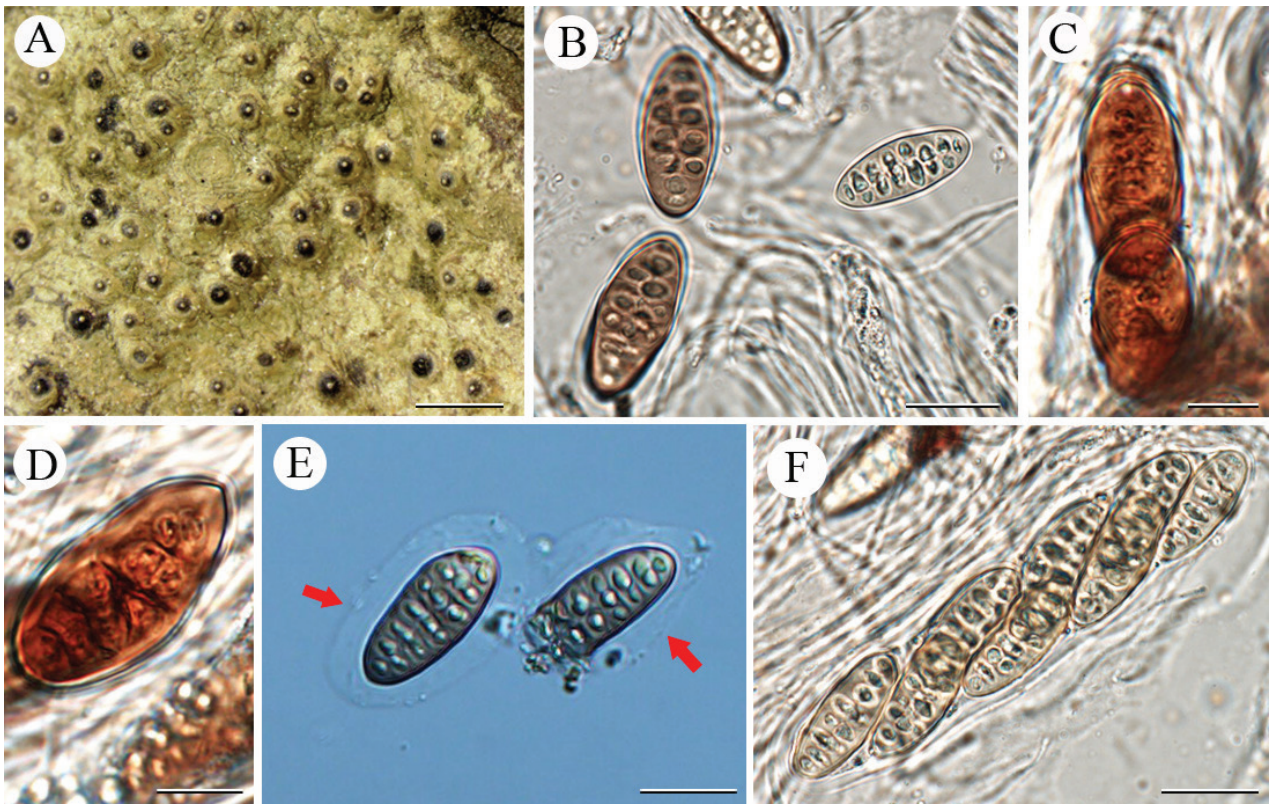

Figure 5. *Pyrenula breutelii* (LCUF GD19285) **A** thallus with ascomata and pseudocyphellae **B** hyaline immature ascospores and brown mature ascospores **C, D** over-mature ascospores with red oil **E** red arrows show gelatinous halo **F** ascus, with 8 ascospores. Scale bars: 1 mm (**A**); 20 µm (**B**); 10 µm (**C, D**); 20 µm (**E, F**).

Chemistry. Thallus UV-. TLC with solvent C showed unidentified black spots at Rf four and five under 254 nm ultraviolet light on fresh plate; unidentified green spot at Rf four on charred plate under daylight; unidentified red spots at Rf three, four and five, unidentified red and black spots at Rf five on charred plate under 365 nm ultraviolet light (Suppl. material 3).

Additional specimens examined. China • Guangdong Province, Guangzhou City, South China Botanical Garden, Chinese Academy of Sciences, Australian Garden, Energy Road, 23°10'44"N, 113°21'20"E, alt. 26 m, on bark, 20 January 2019, Z.T. Yao (LCUF GD19285; GenBank PP692375 for ITS and PP692475 for LSU). China • Guangdong Province, Guangzhou City, South China Botanical Garden, Chinese Academy of Sciences, Australian Garden, Energy Road, 23°10'44"N, 113°21'20"E, alt. 26 m, on bark, 20 January 2019, Z.T. Yao (LCUF GD19286; GenBank PP692376 for ITS, PP692476 for nuLSU and PP659692 for mtSSU).

Habitat and distribution. Growing on tree bark of pantropical forests. Previously reported from the U.S.A (Müller 1885). Newly reported for China.

Notes. The morphology and anatomy characteristics of the Chinese specimens correspond to *Pyrenula breutelii* (Müll. Arg.) Aptroot described from St Thomas, *Breutel*, ex hb. Hampe. *Pyrenula* macularis is distinguished by larger ascomata (0.3–1.5 mm), larger ascospores (35–45 × 14–16) µm and less locules (1–3) (Zahlbruckner 1930). In the protolog, TLC and KI result was not mentioned and molecular sequences were not provided. Here, we provide TLC, KI result and ITS and nuLSU sequences. Because the difference in ascospores between *P. macularis* and *P. breutelii* is not very significant, *P. macularis* was

synonymized with *P. breutelii* (Aptroot 2012; Aptroot et al. 2013). But the phylogenetic result and TLC result proves they are two different species. This is the first report of *P. breutelii* in China. Although *P. breutelii* clustered with *P. thelomorpha* with high support (1/100), they can be distinguished easily in anatomical characters. *P. thelomorpha* has no red or orange oil in over-mature ascospores and more locules (8 rows of c. 3–8 locules) (Aptroot 2009).

***Pyrenula macularis* (Zahlbr.) R.C. Harris**
MycoBank No: 134429
Fig. 6

Basionym. *Anthracothecium maculare* Zahlbr., *Mycologia* 22: 70 (1930).

Holotype. Yauco, Porto Rico [Puerto Rico], 30 Dec. 1915.

Description. Thallus corticolous, crustose, olive-green in the field and khaki after drying, surface dull, corticate with abundant pseudocyphellae, UV-. Apothecia perithecioid, conical, dispersed, aggregated occasionally when crowded, with crystals, immersed in the thallus, small, to 0.3 mm wide at the early developmental stage, then the sides partly covered by the thallus. Excipulum carbonized when mature and falls apart when over-mature. Ostioles apical, white. Hamathecium not inspersed, IKI+ red. Ascospores 8 per ascus, subbiserial, fusiform, with pointed or blunt ends, (33–)37–50 × (13–)14–16 µm, hyaline to brown, muriform, with c. 8 × 1–3 locules, lumina rounded, old spores containing globules of red oily substance.

Chemistry. Thallus UV-. TLC with solvent C showed unidentified black spots at Rf two, four and five under 254 nm ultraviolet light on fresh plate; unidentified green spot at the dividing line of Rf four and five on charred plate under daylight; unidentified red spots at Rf three, four and red spots at Rf five on charred plate under 365 nm ultraviolet light (Suppl. material 4).

Additional specimens examined. China • Hunan Province, Wugang City, Yun Shan, Shuanghua Pavilion, 26°39'28"N, 110°36'37"E, alt. 730 m, on bark of *Zelkova serrata*, 28 April 2018, Z.F. Jia (LCUF HNX18016; GenBank PP692368 for ITS). China • Hunan Province, Wugang City, Yun Shan, Shuanghua Pavilion, 26°39'28"N, 110°36'37"E, alt. 730 m, on bark of *Zelkova serrata*, 28 April 2018, Z.F. Jia (LCUF HNX18017; GenBank PP692369 for ITS). China • Hunan Province, Wugang City, Yun Shan, Shuanghua Pavilion, 26°39'28"N, 110°36'37"E, alt. 730 m, on bark of *Zelkova serrata*, 28 April 2018, Z.F. Jia (LCUF HNX18018; GenBank PP659691 for mtSSU, PP692370 for ITS and PP692473 for nuLSU).

Habitat and distribution. Growing on exposed tree in pantropical forest. Previously reported from Porto Rico (Zahlbruckner 1930), U.S.A. (Harris 1989), Australia (Aptroot 2009), Puntarenas (Aptroot et al. 2008), Muri Lagoon (Mccarthy 2000), HongKong (Aptroot and Seaward 1999) and Taiwan (Aptroot 2003) of China.

Notes. The morphology and anatomy characteristics of the Chinese specimens correspond to *Pyrenula macularis* (Zahlbr.) R.C. Harris described from Yauco, Porto Rico. *P. breutelii* is distinguished by different lichen substances (Suppl. material 4), smaller ascomata (0.3–0.5 mm), smaller ascospores ((23–)25–37(–41) × (10–)12–15(–18)) µm and more locules (1–4). *P. macularis* (no. nr. 5 and 6) has two more black spots at Rf two under 254 nm ultraviolet light on fresh plate than *P. breutelii* (no. nr. 2 and 3) (Suppl. material 4). In the

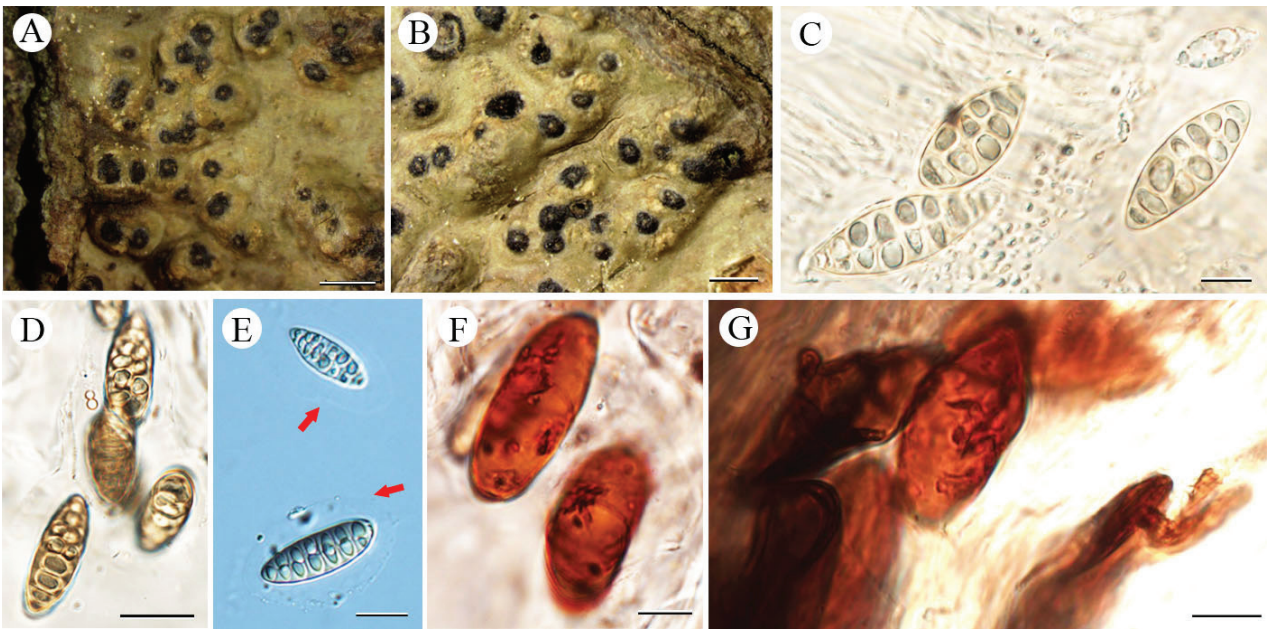

Figure 6. *Pyrenula macularis* (LCUF HNX18017) **A, B** thallus with ascomata and pseudocyphellae **C, D** ascospores at different development stages **E** ascospores with gelatinous halo shown by red arrows **F, G** over-mature ascospores with orange oil. Scale bars: 1 mm (**A, B**); 10 µm (**C**); 20 µm (**D, E**); 10 µm (**F, G**).

protolog, TLC and KI result was not mentioned and molecular sequences were not provided. Here, we provide TLC, KI result and ITS, nuLSU sequences. This species has previously been reported in China only in Hong Kong (Aptroot and Seaward 1999) and Taiwan (Aptroot 2003). Because the difference in ascospores between *P. macularis* and *P. breutelii* is not very significant, *P. macularis* was synonymous with *P. breutelii* (Aptroot 2012; Aptroot et al. 2013). But the phylogenetic result and TLC results prove they are two different species.

Discussion

Because the differences in ascospores between *Pyrenula macularis* and *P. breutelii* are not very significant, *P. macularis* was considered synonymous with *P. breutelii* (Aptroot 2012; Aptroot et al. 2013). But both the phylogenetic and the TLC results prove they are two different species. Similarly, if without molecular phylogenetic analysis and rigorous TLC trials, *P. submacularis* M.Z. Dou & Z.F. Jia, sp. nov. and *P. yunguiensis* M.Z. Dou & Z.F. Jia, sp. nov. might be classified into the same species, and *P. submacularis* M.Z. Dou & Z.F. Jia, sp. nov. might be classified as *P. macularis*. It is obvious that phylogenetic analysis and metabolite detection are crucial in the taxonomic study of *Pyrenula*, but they have been thus far limited to very few specimens, which may partly explain the delimitation problems in *P. quassiicola*, *P. mamillana*, *P. minor*, *P. aspistea* and other taxa revealed in previous and our phylogenetic analysis of this genus (Gueidan et al. 2016; Weerakoon et al. 2012). The delimination of the five species in this study suggests that it is significant to pay attention to the chemical substances in distinguishing phylogenetically informative characters and revealing near-cryptic diversification (Lücking et al. 2021) of *Pyrenula*.

Meanwhile, I carried out the TLC experiments of some remote species as Suppl. materials 5, 6. The *Pyrenula* sp., which was one new record in China

unpublished and included in the Group 2 of phylogenetic tree, did not produce the same set of terpenoids as the five species described in this article. But it showed two white spots at Rf 2 on the plate C, which might represent the same chemical substances as that *P. macularis* produced. The other species were included in other families, and did not produce the same chemicals as the five species. This seems to suggest that the likelihood of producing the same chemical is positively related to the distance of phylogenetic relationships. In Southern China, there are abundant subtropical to tropical evergreen resources (Zhu 2017). This habitat is favorable for the pyrenocarpous lichens, including *Pyrenula*. However, the genus has not been sufficiently studied in China. Most of *Pyrenula* reported in China were in the checklist of the lichens of Hong Kong and Taiwan (Aptroot and Seaward 1999; Aptroot 2003). Furthermore, the vast majority of *Pyrenula* reported in China were new records and had no molecular data. Our research suggests high species richness of *Pyrenula* is expected to be found when the taxonomic studies of this genus were carried out systematically in China.

Key to the species of *Pyrenula* reported in China

Key A (Ascospores submuriform to muriform).
Key B (Ascospores only transversely septate).

Key A

1 Thallus yellow to orange; anthraquinones pigments K+ pink to purplish ..... ***Pyrenula ochraceoflava* (Nyl.) R.C. Harris**
– Thallus K– or yellowish, anthraquinones absent **2**
2 Ostioles lateral **3**
– Ostioles apical **4**
3 Ascospores < 70 µm long ..... ***Pyrenula astroidea* (Fée) R.C. Harris**
– Ascospores > 70 µm long ..... ***Pyrenula schiffneri* (Zahlbr.) Aptroot**
4 Ascospores < 25 µm long **5**
– Ascospores > 25 µm long **6**
5 Thallus UV+yellow ..... ***Pyrenula confinis* (Nyl.) R.C. Harris**
– Thallus UV ..... ***Pyrenula parvinuclea* (Meyen & Flot.) Aptroot**
6 Old ascospores with orange oil **7**
– Old ascospores without orange oil **11**
7 Ascospores 4/ascus, 70–100(–106) × (17–)21–27(–41) µm, 10–12 × 3–14 locules ..... ***Pyrenula rufotetraspora* M.Z. Dou & Z.F. Jia, sp. nov.**
– Ascospores 8/ascus **8**
8 TLC with solvent C showed one spot with fluorescence at Rf five under 365 nm ultraviolet light, ascospores 40–65 × 16–21(–28) um, 7–9 × 2–7 locules ..... ***Pyrenula submacularis* M.Z. Dou & Z.F. Jia, sp. nov.**
– TLC with solvent C showed no fluorescent spot at Rf five under 365 nm ultraviolet light **9**
9 Most ascospores < 50 µm long **10**
– Ascospores 50–70(–80) × 17–22(–26) µm, 8 × 2–4 locules ..... ***Pyrenula yunguiensis* M.Z. Dou & Z.F. Jia, sp. nov.**

10 Ascospores (23–)25–37(–41) × (10–)12–15(–18) µm, 8 × 1–4 locules, TLC with solvent C showed no black spot at Rf two under 254 nm ultraviolet light ..... ***Pyrenula breutelii* (Müll. Arg.) Aptroot**
– Ascospores (33–)37–50 × (13–)14–16 µm, 8 × 1–3 locules, TLC with solvent C showed two black spots at Rf two under 254 nm ultraviolet light ... .***Pyrenula macularis* (Zahlbr.) R.C. Harris**
11 Ascospores > 80 µm long, mostly 2/ascus **12**
– Ascospores < 80 µm long, mostly 4–8/ascus.....**13**
12 Thallus without pseudocyphellae, ascospores 80–140(–155) µm long..... .....***Pyrenula platystoma* (Müll. Arg.) Aptroot**
– Thallus with pseudocyphellae, ascospores 115–180 µm long..... .....***Pyrenula duplicans* (Nyl.) Aptroot**
13 Locules relatively large and angular, with up to 6 between 2 primary septa.....***Pyrenula leucostoma* Ach.**
– Locules mostly round, at least in the central part of the ascospore with more than 6 between 2 primary septa ....***Pyrenula pyrenuloides* (Mont.) R.C. Harris**

Key B

1 Ostioles pointing in various directions, mostly eccentric to lateral; ascomata sometimes with several chambers connected to joint ostioles.....**2**
– Ostioles apical or, when eccentric, all pointing in the same direction; ascomata with one chamber or each chamber with own ostiole **4**
2 Terminal locules directly against the exospore wall; ascospores 16–25 µm long .....***Pyrenula circumfiniens* Vain.**
– Terminal locules separated from the exospore wall by endospore thickening.....**3**
3 Ascospores 35–45 µm long .....***Pyrenula adacta* Fée**
– Ascospores 18–30 µm long ..... ***Pyrenula acutispora* Kalb & Hafell**
4 Ascospores at least seemingly 4–7-septate; old ascospores with orange oil, thallus often with pseudocyphellae ....***Pyrenula sexlocularis* (Nyl.) Müll. Arg.**
– Ascospores all distinctly 3-septate.....**5**
5 Ascospores (45–)50–60 µm long, thallus without papillae but with pseudocyphellae .....***Pyrenula immissa* (Stirt.) Zahlbr.**
– Ascospores mostly < 50 µm long.....**6**
6 Ascomata erumpent, c. 0.4–0.8 mm diam; thallus with red patches or completely red; ascospores 27–35 µm long.....***Pyrenula cruenta* (Mont.) Vain.**
– Ascomata and thallus without external pigments **7**
7 Ascomata mostly aggregated, with fused walls but with separate ostioles.....**8**
– Ascomata mostly simple, only aggregated as by chance when crowded.... **10**
8 Old ascospores with red oil; hamathecium inspersed, ascospores 28.5–50 × 10–20 µm .....***Pyrenula inspersa* M.Z. Dou & Z.F. Jia**
– Old ascospores without red oil.....**9**
9 Ascospores mostly 21–25 µm long.....***Pyrenula leucotrypa* (Nyl.) Upreti**
– Ascospores mostly 15–20 µm long.....***Pyrenula anomala* (Ach.) Vain.**

10 Old ascospores with orange oil **11**
– Old ascospores without orange oil **14**
11 Ascospores < 35 µm long **12**
– Ascospores > 35 µm long **13**
12 Terminal locules directly against the exospore wall ..... ***Pyrenula apiculata* M.Z. Dou & Z.F. Jia**
– Terminal locules separated from the exospore wall by endospore thickening ..... ***Pyrenula bahiana* Malme**
13 Hamathecium IKI-; no substances detected by TLC ..... ***Pyrenula thailandica* Aptroot**
– Hamathecium IKI+ red; TLC showed an unidentified spot at Rf four under 254 nm ultraviolet light using solvent C ..... ***Pyrenula thailandicoides* M.Z. Dou & Z.F. Jia**
14 Terminal locules all directly against the exospore wall **15**
– Terminal locules mostly (at least in mature ascospores) separated from the exospore wall by endospore thickening **19**
15 Thallus UV+ yellow ..... ***Pyrenula pseudobufonia* (Rehm) R.C. Harris**
– Thallus UV **16**
16 Hamathecium inspersed **17**
– Hamathecium not inspersed ..... ***Pyrenula nitidula* (Bres.) R.C. Harris**
17 Ascospores all < 16 µm long ..... ***Pyrenula cayennensis* Müll. Arg.**
– Ascospores partly > 16 µm long **18**
18 Hamathecium inspersed only in the upper part .. ***Pyrenula acutalis* R.C. Harris**
– Hamathecium totally inspersed ... ***Pyrenula fetivica* (Krempelh.) Müll. Arg**
19 Hamathecium inspersed **20**
– Hamathecium not inspersed **24**
20 Central ascospore locules elongated ..... ***Pyrenula subelliptica* (Tuck.) R.C. Harris**
– Central ascospore locules transversely lenticular to rounded **21**
– Ascomata mostly < 0·7 mm diam; ascospores 18–20 µm long; thallus and ascomata without any anthraquinone ..... ***Pyrenula subglabrata* (Nyl.) Müll. Arg.**
– Ascomata mostly > 0·7 mm diam **22**
22 Ascospores mostly 10–20 µm long ..... ***Pyrenula mamillana* (Ach.) Trevis.**
– Ascospores mostly > 20 µm long **23**
23 Ascospores rounded, uniseriate in the ascus ..... ***Pyrenula massariospora* (Starb.) R.C. Harris**
– Ascospores at least at one end pointed, biseriate in the ascus ..... ***Pyrenula acutalis* R.C. Harris**
24 Thallus UV+yellow ..... ***Pyrenula dermatodes* (Borrer) Schaer**
– Thallus UV− or greenish/whitish reflecting **25**
25 Ascospores mostly > 25 µm long **26**
– Ascospores mostly < 25 µm long **30**
26 Ascospores 36–45 µm long, without black granules at the tips ..... ***Pyrenula subducta* (Nyl.) Müll. Arg.**
– Ascospores < 40 µm long, without black granules at the tips **27**
27 Ascomata mostly > 0·7 mm diam ..... ***Pyrenula complanata* (Mont.) Trevis.**
– Ascomata mostly < 0·7 mm diam **28**

28 Ascospores 32–42 µm long ..... ***Pyrenula punctella* (Nyl.) Trevis.**
– Ascospores mostly 25–37 µm long..... **29**
29 Central locules much wider than long, ascomata conical, emergent, thallus without pseudocyphellae..... ***Pyrenula mastophora* (Nyl.) Müll. Arg.**
– Central locules more or less rounded, ascomata somewhat rounded, often partly immersed in the thallus, thallus often with pseudocyphellae..... ..... ***Pyrenula quassiaecola* (Fée) Fée**
30 Ascospores mostly 21–25 µm long..... **31**
– Ascospores mostly < 21 µm long..... **34**
31 Ascomata with red, KOH+ purple crystals inside; ascomata > 0·5 mm diam ..... ***Pyrenula nitida* (Weigel) Ach.**
– Ascomata without red crystals..... **32**
32 Ascospores with angular diamond-shaped locules..... ..... ***Pyrenula micheneri* R.C. Harris**
– Ascospores with rounded or quadrangular locules **33**
33 Ascospores with at least one pointed end .... ***Pyrenula acutispora* Kalb & Hafellner**
– Ascospores with rounded ends..... ..... ***Pyrenula submastophora* Ajay Singh & Upreti**
34 Ascospores mostly < 15 µm long..... **35**
– Ascospores mostly > 15 µm long..... **36**
35 Ascospores 6–8 µm wide..... ***Pyrenula brunnea* Fée**
– Ascospores 4–6 µm wide..... ***Pyrenula aspistea* (Ach.) Ach**
36 Ascomata > 0·7 mm diam ..... ***Pyrenula scutata* (Stirt.) Zahlbr.**
– Ascomata < 0·7 mm diam..... **37**
37 Ascospores with dark bands between the locules .... ***Pyrenula confoederata* R.C. Harris**
– Ascospores without dark bands..... ***Pyrenula aggregata* (Fée) Fée**

Conflict of interest

The authors have declared that no competing interests exist.

Ethical statement

No ethical statement was reported.

Funding

This research was supported by the National Natural Science Foundation of China (No. 32300005).

Author contributions

M.-Z.D. conceived and designed the study. M.-Z.D. and J.-C.L. generated the DNA sequence data. M.-Z.D., Y.-S.H., J.-C.L. and A.A. performed the phenotypic assessment of the material. M.-Z.D., Z.-F.J. and A.A. analyzed the data. M.-Z.D. and Z.-F.J. checked issues related to nomenclatural articles. M.-Z.D. wrote the manuscript draft. M.-Z.D., Z.-F.J. and A.A. revised the manuscript. All authors have read and agreed to the published version of the manuscript.

Abstract

A novel genus, *Paradingleyomyces* was introduced to accommodate *Pa. lepidopterorum* **sp. nov.**, based on a multigene phylogenetic analysis and its distinct morphological characteristics. Maximum likelihood (ML) and Bayesian inference analyses (BI) of ITS, SSU, LSU, *tef-1α*, *rpb1*, and *rpb2* sequence data shown that *Pa. lepidopterorum* formed an independent lineage nested between *Perennicordyceps* and *Dingleyomyces*. Morphologically, *Paradingleyomyces* is distinguished from *Perennicordyceps* by the presence of a white subiculum on the stromata of *Ophiocordyceps* cf. *cochlidiicola*. Perithecia are produced sporadically from the base to the apex of the stromata, and the secondary ascospores exhibit a notable length-to-width ratio. These characteristics distinguish *Paradingleyomyces* from *Perennicordyceps* which exhibits tortuous, branched, clavate to cylindrical stromata with rhizomorphs, parasitism of coleopteran and hemipteran larvae, and colonizes a broader range of fungal hosts. Additionally, perithecia in *Perennicordyceps* typically arise from the middle to the upper regions of the stromata, with secondary ascospores displaying a comparatively lower length-to-width ratio. *Paradingleyomyces* is morphologically identical to *Dingleyomyces* in its direct production of superficial perithecia on the stromata of *Ophiocordyceps* species. However, the phylogenetic analysis indicates that *Paradingleyomyces* and *Dingleyomyces* are not congeneric. Moreover, this study introduces another novel species, *Polycephalomyces tengchongensis*, and a novel sexual morph of *Pleurocordyceps yunnanensis*. Dimorphic phialides and conidia of *Pleurocordyceps parvicapitata* were observed and described for the first time based on a fresh collection from Tengchong County, Yunnan Province, China.

Key words: Entomopathogenic fungi, new genus, phylogeny, taxonomy

(Hypocreales, Polycephalomycetaceae) from Yunnan Province, China. MycoKeys 110: 185–210. https://doi.org/10.3897/mycokeys.110.134132

Introduction

Polycephalomyces was introduced as an entomopathogenic genus by Kobayasi (1941), based on the asexual morph of the *Po. formosus*, which was characterized by polycephalous synnemata with white to pale yellow conidial masses on the tips. Species of *Polycephalomyces* form parasitic associations with a wide range of hosts, including insects, fungi and myxomycetes (Shrestha et al. 2017; Xiao et al. 2023). Among these, *Ophiocordyceps* species are the most common hosts to *Polycephalomyces*. For instance, *Polycephalomyces sinensis* was found as a hyperparasite on *Ophiocordyceps sinensis*, *Po. ramosus* on *Hirsutella guignardii* and *Pleurocordyceps lianzhouensis* on *O. crinalis* (Massee 1895; Kobayasi 1941; Kepler et al. 2013; Wang et al. 2014). Members of *Polycephalomyces* were expanded to include sexual species that were phylogenetically distant from the *Ophiocordyceps* sensu stricto by Kepler et al. (2013). In this study, the sexual morph of *Polycephalomyces* was described as possessing firm, pliant, multifurcating stromata, perithecia that are either superficial or immersed in an apical or subapical pulvinate cushion, filiform asci and disarticulating ascospores. The taxonomic placement of *Polycephalomyces* remained uncertain until Quandt et al. (2014) classified it within the family Ophiocordycipitaceae based on phylogenetic analyses of combining SSU, LSU, *tef-1α*, *rpb1* and *rpb2* sequence. *Perennicordyceps* was later established by Matočec et al. (2014) to accommodate four species (*Perennicordyceps cuboidea*, *Pe. paracuboidea*, *Pe. prolifica*, and *Pe. ryogamiensis*), which were previously classified under *Polycephalomyces*, based on comprehensive morphological characteristics and molecular data analyses. *Perennicordyceps* is characterized by the presence of superficial perithecia and acremonium-like or hirsutella-like asexual morphs (Matočec et al. 2014; Hyde et al. 2018; Wei et al. 2022). Wang et al. (2021) established *Pleurocordyceps* to accommodate ten species that previously were placed in *Polycephalomyces*. An increasing number of polycephalomyces-like species have been added to *Polycephalomyces*, *Perennicordyceps*, and *Pleurocordyceps*, contributing to a more refined understanding of their natural classification and phylogenetic relationships (Wang et al. 2014; Wang et al. 2015a, 2015b; Liang et al. 2016; Crous et al. 2017a; Xiao et al. 2018, 2023; Yang et al. 2020). Xiao et al. (2023) constructed a backbone tree of Hypocreales using extensive taxon sampling, and the result clearly showed that *Polycephalomyces*, *Perennicordyceps*, and *Pleurocordyceps* form a monophyletic clade distinct from Ophiocordycipitaceae. As a result, a new family, Polycephalomycetaceae, was established to accommodate these three genera. It is worth noting that in the phylogenetic analysis conducted by Xiao et al. (2023), Polycephalomycetaceae was identified as a sister clade with Ophiocordycipitaceae. However, in the study conducted by Wei et al. (2022), Polycephalomycetaceae was found to form a sister clade to Clavicipitaceae. These contrasting findings suggest that the phylogenetic relationship between Polycephalomycetaceae and other hypocrealean families requires further confirmation through future research, incorporating more comprehensive taxon sampling. Therefore, discovering hidden or yet unknown species within Polycephalomycetaceae is essential for improving our understanding of this family's evolutionary position.

During our ongoing exploration of the diversity of entomopathogenic fungi and their associated fungi in Yunnan Province, China, several polycephalomyces-like species were found from various hosts including *Elaphomyces* sp., lepidopteran

larvae, *Ophiocordyceps nutans*, and *Perennicordyceps* cf. *elaphomyceticola*. This study aims to assess the phylogenetic relationships of these samples with existing species of Polycephalomycetaceae using a concatenated SSU, ITS, LSU, *tef-1α*, *rpb1* and *rpb2* sequences, as well as detailed morphological analyses. The morphological observations and phylogenetic analyses allowed us to introduce a new genus, *Paradingleyomyces*, a new species, *Polycephalomyces tengchongensis*, a new sexual morph of *Pleurocordyceps yunnanensis*, and a new collection of *Pleurocordyceps parvicapitata*. These findings expand our understanding of this unique group of entomopathogens and mycoparasites, offering fresh and novel insights into their morphology, ecology and evolutionary relationships.

Materials and methods

Morphological study and isolation

To explore the diversity of fungal resources, samples were collected from tropical and subtropical forests rich in evergreen trees diversity in southwestern China. Morphological studies followed the guidelines proposed by Senanayake et al. (2020). Specimens were placed in small plastic boxes and transported to the laboratory for isolation. Both specimens and colonies were photographed using a Canon 6D camera equipped with a 100 mm MACRO lens for detailed morphological documentation. Fruiting bodies were examined, and free-hand sections were prepared using a stereomicroscope (Leica S9E). Slides containing sectioning of the fertile parts were mounted for microscopic observation with a Leica DM2500 compound microscope equipped with a digital camera. Micro-morphological characters, including ascomata, perithecia, peridium texture, asci, ascospores, secondary ascospores, conidiophores, phialides, and conidia were photographed and measured by using the Leica microsystem for precise documentation and analysis. A small mass of tissue from the fertile parts of the fungus or insect bodies was transferred to potato glucose agar (PDA) plate using sterile inoculation needles and incubated at 25 °C to obtain pure isolates (Wen et al. 2014; Aini et al. 2020; Peng et al. 2024). Freshly collected specimens were dried using silica gel to preserve them as dry specimens. The cultures were deposited in the Herbarium of Kunming Institute of Botany Culture Collection (KUNCC; http://english.kib.cas.cn/) and the dry specimens were deposited in the Herbarium of Cryptogams, Kunming Institute of Botany of the Chinese Academy of Sciences (KUN; http://kun.kingdonia.org/).

DNA extraction, PCR amplification and sequencing

DNA was extracted from fresh specimens and cultures using the E.Z.N.A.™ Fungal DNA MiniKit (Omega Biotech, CA, USA) following the manufacturer's protocols. Polymerase chain reaction (PCR) was performed to amplify six loci: the small subunits nuclear of rDNA (SSU), the internal transcribed spacer (ITS), the large subunit nuclear of rDNA (LSU), the transcription elongation factor-1α (*tef-1α*), the partial RNA polymerase II largest subunit (*rpb1*) and the partial RNA polymerase II second largest subunit (*rpb2*). The primer pairs used for amplifying the six loci were as follows: NS1 and NS4 for SSU (White et al. 1990), ITS5 and ITS4 for ITS (White et al. 1990), LROR and LR5 for LSU (Vilgalys and Hester 1990), 983F and 2218R for *tef-1α* (Rehner and Buckley 2005), CRPB1A and RPB1Cr for *rpb*1 (Castlebury et al.

2004), and RPB2-5F and RPB2-7R for *rpb2* (Liu et al. 1999). Amplification reaction was performed in a 50 µL reaction volume containing 4 µL of DNA template, 2 µL of each forward and reverse primers (10 pM), 22 µL of 2×*Taq* PCR StarMix with Loading Dye (GenStar) and 20 µL of twice-sterilized water. The amplification conditions for ITS, LSU, SSU, *tef-1α*, *rpb1*, and *rpb2* were as follows: (1) 3 min at 94 °C, (2) 33 cycles of denaturation at 94 °C for 30 s, annealing (ITS at 52 °C for 50 s, SSU at 47 °C for 1 min 20 s, LSU at 50 °C for 30 s, *tef-1α* at 58 °C for 50 s, *rpb1* and *rpb2* at 51 °C for 40 s), and elongation (ITS at 72 °C for 45 s, SSU and LSU at 72 °C for 1min 50 s, *tef-1α* at 72 °C for 1 min, *rpb1* and *rpb2* at 72 °C for 1 min 20 s), and (3) final extension at 72 °C for 10 min. The PCR products were sent to Tsingke Biological Technology in Chongqing, China, for sequencing, and the resulting sequences were submitted to GenBank for the assignment of accession numbers.

Phylogenetic analysis

The newly generated sequences were checked and assembled using BioEdit v.7.0.5.3 (Hall et al. 2011). The assembled sequences were then subjected to BLAST searches in the GenBank database of National Center for Biotechnology Information (NCBI) to confirm their identities. Taxa used for phylogenetic analyses were chosen based on relevant publications and presented in Table 1. The individual gene was aligned using MAFFT (Katoh and Standley 2013). Trimal v1.2 was used to remove alignments sites that did not achieve a user specified gap score of 0.6 (Capella-Gutiérrez et al. 2009). The trimmed alignments were concatenated using FasParser 2.10.0 (Sun 2017). The final combined alignment was subjected to Maximum likelihood (ML) and Bayesian inference (BI) analyses. ML analysis was performed using IQ-TREE 1.6.12, with branch support estimated from 1000 ultrafast bootstraps replicates (Minh et al. 2020).MrModelTest v. 2.3 (Nylander 2004) was used to determine the best evolutionary model for Bayesian inference analysis according to the Akaike Information Standard (AIC). The best-fit models GTR+I+G, were determined for SSU, ITS, LSU, *tef1-α*, *rpb1*, and *rpb2*. The BI analysis was carried out using MrBayes on XSEDE (3.2.7a) through the CIPRES Science Gateway V 3.3 platform (Miller et al. 2010). Four Markov chain Monte Carlo (MCMC) simulations were run for 50,000,000 generations, sampling every 1000 generations and discarding the first 25% as burn-in. The remaining trees were used to calculate Bayesian posterior probabilities. The resulting trees were visualized using FigTree v1.4.3 (Rambaut 2012). To determine whether the taxa represented new species or new records, the guidelines of Jeewon and Hyde (2016) were followed.

Results

Phylogenetic analyses

The phylogenetic analysis was constructed using sequence data from six loci, representing 112 Polycephalomycetaceae taxa. The alignment comprised 5142 base pair (bp) characters, including gaps (1026 bp for SSU, 602 bp for ITS, 845 bp for LSU, 901 bp for *tef-1α*, 711 bp for *rpb1*, and 1057 bp for *rpb2*). Of these, 3648 characters were constant, 1310 variable characters parsimony-uninformative and 1936 characters parsimony-informative. The likelihood of the best-scoring ML tree was -26079.662.

Table 1. Accession numbers of taxa used in this study. Newly generated sequences are indicated in bold. [T] Represents type strain, type specimens or neotype.

In the phylogenetic analyses (Fig. 1), two strains of *Tolypocladium ophioglossoides* (NBRC 100998 and NBRC 106330) were used as outgroup taxa. In the multi-locus phylogenetic tree (Fig. 1), our specimens were distributed across four clades, representing one new genus, one new species and three known species. The strain of *Paradingleyomyces lepidopterorum* (HKAS 131926, HKAS 131927 and HKAS 131921) formed a distinct clade, positioned between *Dingleyomyces* and *Perennicordyceps*, with maximum statistical support (MLBS = 100%, BIPP = 1.00). *Polycephalomyces tengchongensis* (HKAS 131923) branches off from *Polycephalomyces formosus* with significant support (MLBS = 100%, BIPP = 1.00). *Pleurocordyceps yunnanensis* (HKAS 131922) groups with *Pleurocordyceps yunnanensis* (YHH PY1006 and YHC PY1005) with strong support (MLBS = 84%, BIPP = 0.99). *Pleurocordyceps parvicapitata* (HKAS 131924), along with its isolate KUNCC23-16075 and the isolate KUNCC23-16074 (which was isolated from the sclerotium of specimen HKAS 131925) clusters with *Pleurocordyceps parvicapitata* with adequate support (MLBS = 90%, BIPP = 1.00). *Perennicordyceps elaphomyceticola* (HKAS 131925), which represents the host of *Pleurocordyceps parvicapitata* phylogenetically clusters with *Perennicordyceps elaphomyceticola* (MFLU 21-0262, MFLU 21-0263, MFLU 21-0264, MFLU 21-0266, and NTUCC 17-022) with strong support (MLBS = 100%, BIPP = 1.00).

Figure 1. Phylogenetic tree of Polycephalomycetaceae based on a concatenated data matrix of SSU, ITS, LSU, *tef-1a*, *rpb1*, and *rpb2*. Bootstrap values greater than or equal to 75% and Bayesian posterior probabilities greater than or equal to 0.80 are shown at the respective nodes. Newly added taxa from this study are highlighted in red.

Taxonomy

***Paradingleyomyces* Y. Wang tris & T. C. Wen, gen. nov.**
Index Fungorum: IF901540

Etymology. Morphologically resembling the genus *Dingleyomyces*.

Type species. *Paradingleyomyces lepidopterorum* Y. Wang tris & T. C. Wen, sp. nov.

Description. Parasitic on *Ophiocordyceps* cf. *cochlidiicola*. Sexual morph: Stroma absent. ***Perithecia*** forming from white subiculum covering stromata of *Ophiocordyceps* cf. *cochlidiicola*, superficial, scattered, brown, ovoid or ellipsoidal. ***Asci*** cylindrical with a thickened cap, attenuated toward the base. ***Ascospores*** filiform, hyaline, disarticulating into many cylindrical secondary ascospores at maturity. ***Secondary ascospores*** cylindrical, aseptate, smooth-walled, with truncated ends. Asexual morph: Undetermined.

Notes. Both *Paradingleyomyces* and *Dingleyomyces* are monotypic genera and share similar morphological characteristics, including the formation of superficial perithecia on a white subiculum, cylindrical asci with thickened caps, and filiform ascospores that disarticulate into cylindrical secondary ascospores. Additionally, the type species of both genera occur as hyperparasites on *Ophiocordyceps* species (Johnston and Park 2023). However, multigene phylogenetic analysis revealed that these two genera exhibit a paraphyletic relationship, indicating they are not congeneric. *Paradingleyomyces* can be easily distinguished from *Perennicordyceps* by its reduced stromata, whereas *Perennicordyceps* features cylindrical to clavate, branched stromata with prominent rhizomorphs immersed in the substrate, and perithecia forming from the middle to upper parts of the stromata (Ban et al. 2009; Xiao et al. 2019, 2023).

***Paradingleyomyces lepidopterorum* Y. Wang tris & T. C. Wen, sp. nov.**
Index Fungorum: IF901541
Fig. 2

Etymology. This epithet is named after the order of its primary host: Lepidoptera.

Description. Parasitic on *Ophiocordyceps* cf. *cochlidiicola*. ***Stromata*** of host fungus are 55–180 mm in length, 1–3 mm in width, multiple, unbranched, brown at base becoming off-white toward the apex, fibrous, narrowly cylindrical to filiform. Sexual morph: ***Subiculum*** white, cottony, covering the stromata of host fungus. ***Perithecia*** 240–690 × 110–360 µm ($\bar{x}$ = 430 × 228 µm, n = 25), emerging from subiculum, superficial, scattered or dense, flesh-colored, ovoid or ellipsoidal. ***Asci*** 150–400 × 3–8 µm ($\bar{x}$ = 289 × 5 µm, n = 30), cylindrical, hyaline, with an apical cap. ***Apical cap*** 3–5 × 1–4 µm ($\bar{x}$ = 3.8 × 2.3 µm, n = 40), hemispherical. ***Ascospores*** filiform, multiseptate, breaking into many secondary ascospores at maturity. ***Secondary ascospores*** 2–4 × 0.5–1 µm ($\bar{x}$ = 2.5 × 0.9 µm, n = 50), hyaline, aseptate, smooth-walled, cylindrical with truncated ends. Asexual morph: Undetermined.

Distribution. China: Yunnan Province.

Material examined. ***Holotype:*** China • Yunnan Province, Tengchong County, Houqiao Town; 5 Nov. 2022; Collected by Yi Wang; Parasitic on the stromata of

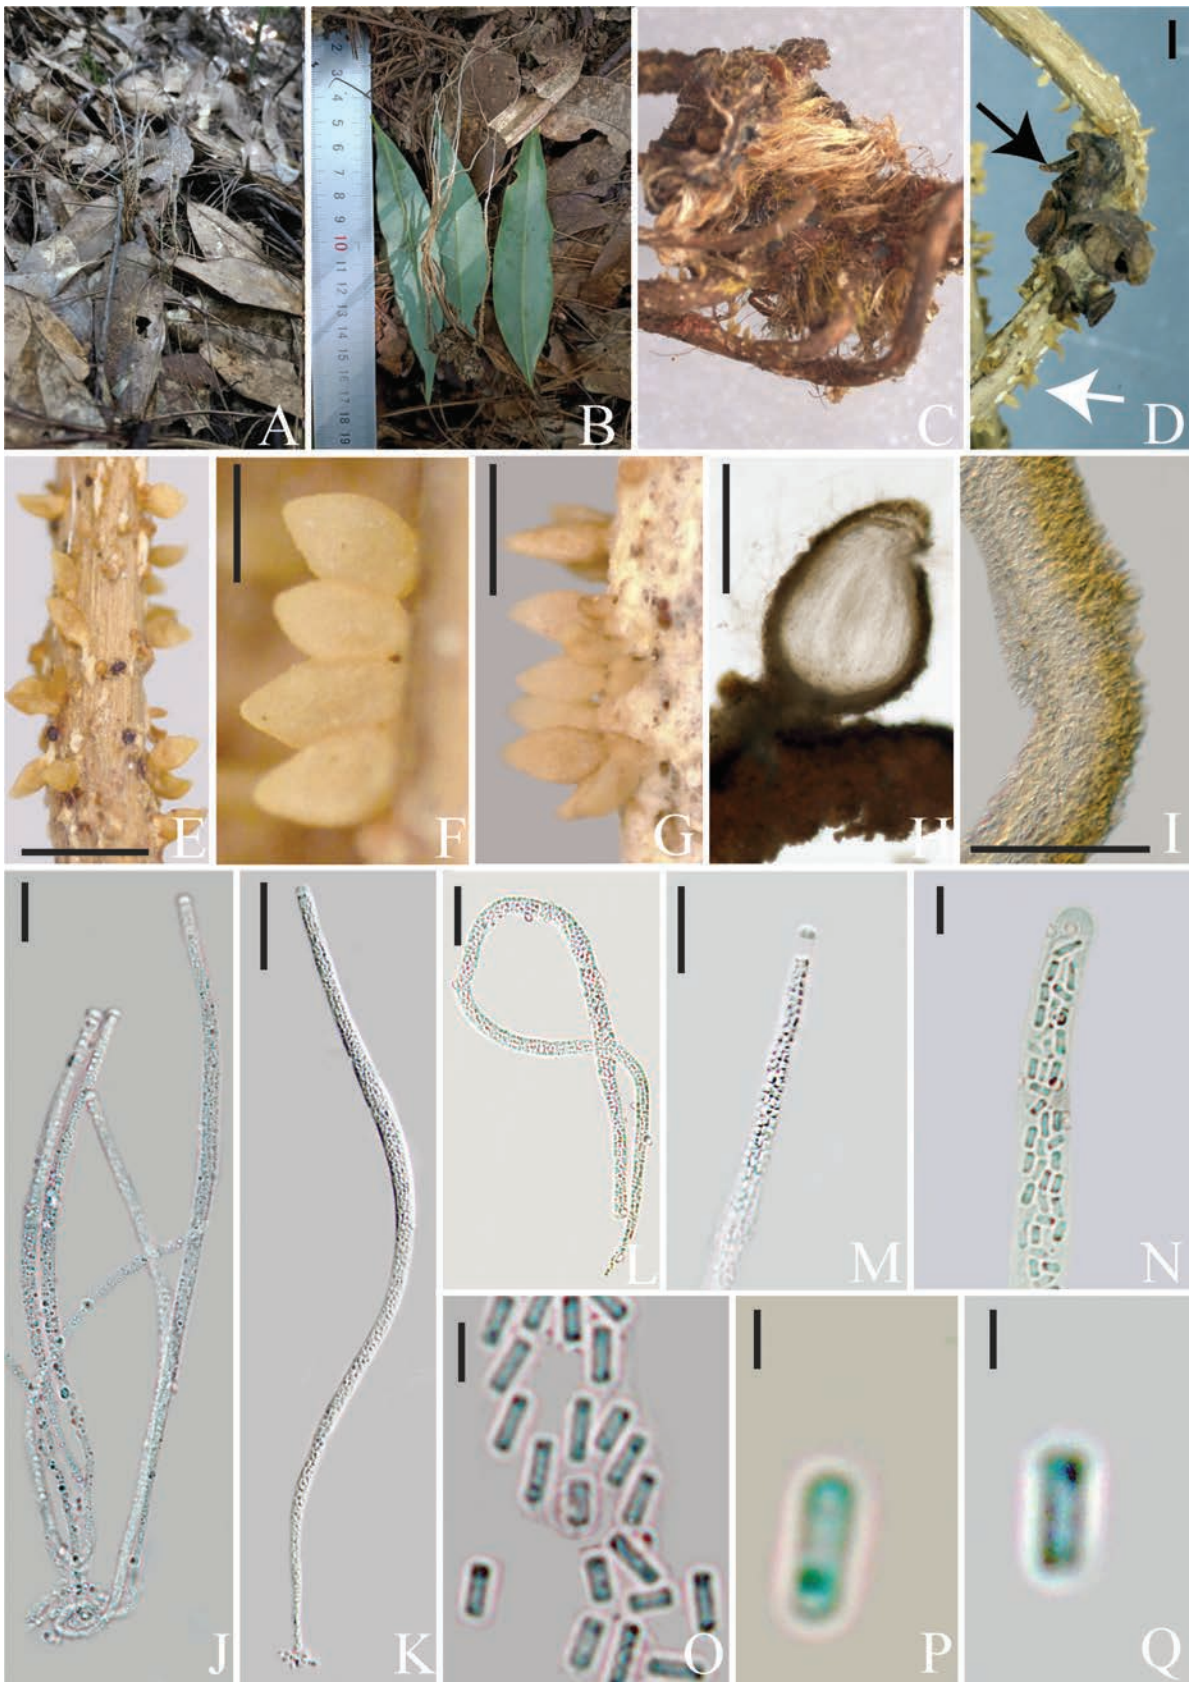

Figure 2. *Paradingleyomyces lepidopterorum* (HKAS 131926, **holotype**) **A** habitat **B** stromata growing from the host **C** host **D** perithecia of *Pa. lepidopterorum* (white arrow) and *Ophiocordyceps* cf. *cochlidiicola* (black arrow) **E–G** perithecia forming on white subiculum **H** vertical section of perithecium. I Peridium **J–L** asci **M, N** apical cap of asci **O–Q** secondary ascospores. Scale bars: 1 mm (**E–G**); 500 µm (**H**); 100 µm (**I**); 50 µm (**J, K**); 25 µm (**L**); 20 µm (**M, N**); 5 µm (**O–Q**).

Perennicordyceps cf. *elaphomyceticola*; GYY543H (HKAS 131926) • ***Paratypes:*** *ibid*; GYY543Z (HKAS131927), TC327 (HKAS 131921).

Notes. *Paradingleyomyces lepidopterorum* lives as a hyperparasite on the remnant stromata of *Ophiocordyceps* cf. *cochlidiicola*. The aging stromata of the host fungus become covered with the perithecia of the hyperparasitic fungus, which closely resemble those of the host. However, the key distinguishing feature is that the hyperparasitic perithecia are flesh-colored and grow on a white subiculum, whereas the host's perithecia are dark brown and directly connected to the stroma (Fig. 2D). *Paradingleyomyces lepidopterorum* and *Dingleyomyces lloydii* are morphologically very similar, but they can be easily distinguished from *Perennicordyceps* species by the presence of a white subiculum from which the perithecia arise (Table 2). In contrast, *Perennicordyceps* is characterized by cylindrical to clavate, branching stromata with the host and rhizomorphs embedded in the substrate. *Dingleyomyces lloydii* produce crown-like perithecia on the stromata of *Ophiocordyceps hauturu* and *O. robertsii*, while the perithecia of *Pa. lepidopterorum* sporadically form on the stromata of *O.* cf. *cochlidiicola*.

Polycephalomyces tengchongensis **Y. Wang tris & T. C. Wen, sp. nov.**
Index Fungorum: IF901449
Fig. 3

Etymology. Named after the location where the type specimen was found, Tengchong County, Yunnan Province.

Description. Parasitic on *Perennicordyceps* cf. *elaphomyceticola*. Sexual morph: Undetermined. Asexual morph: ***Synnemata*** 18.7 mm long, 1–2 mm wide, cylindrical, white, growing in small group on stromata of *Perennicordyceps* cf. *elaphomyceticola*. ***Fertile parts*** yellowish, with conidial mass forming on middle part of synnemata. ***Phialides*** dimorphic. ***α-phialides*** 9–20 × 1–2 µm ($\bar{x}$ = 12.3 × 1.2 µm, n = 45), phialidic, subulate, hyaline, smooth-walled, arranged in a parallel palisade-like layer around the fertile part. ***α-conidia*** 1–3 µm ($\bar{x}$ = 2 µm, n = 45), globose, hyaline.

Culture characters. Colonies on PDA attaining a diam. of 28–31 mm in 14 days at 25 °C, white, leathery, radially striate, reverse dark brown and turns pale outward. ***β-phialides*** 18–44 × 1–3 µm ($\bar{x}$ = 26.7 × 1.2 µm, n = 30), phialidic, lanceolate, smooth-walled. ***β-conidia*** 3–7 × 1.5–3 µm ($\bar{x}$ = 3.9 × 2.2 µm, n = 45), ellipsoidal to broadly fusiform, hyaline, aseptate, smooth-walled.

Material examined. China • Yunnan Province, Tengchong County, Houqiao Town; 5 Nov. 2022; Collected by Yi Wang; Parasitic on the stromata of *Perennicordyceps* cf. *elaphomyceticola*; GYY547 (HKAS 131923, ex-holotype living culture: KUNCC23-16073).

Notes. The newly described species *Polycephalomyces tengchongensis* is closely related to *Po. formosus* with strong support (MLBS = 100%, MIPP = 1.00, Fig. 1). However, *Polycephalomyces tengchongensis* is distinct from *Po. formosus* in several aspects. It parasitizes *Perennicordyceps* cf. *elaphomyceticola* and produces synnemata without well-defined stipe and a fertile head but features dimorphic phialides and conidia. In contrast, *Po. formosus* has stipitate synnemata with a fertile head at the tip and produces only one type of phialides and conidia (Xiao et al. 2023).

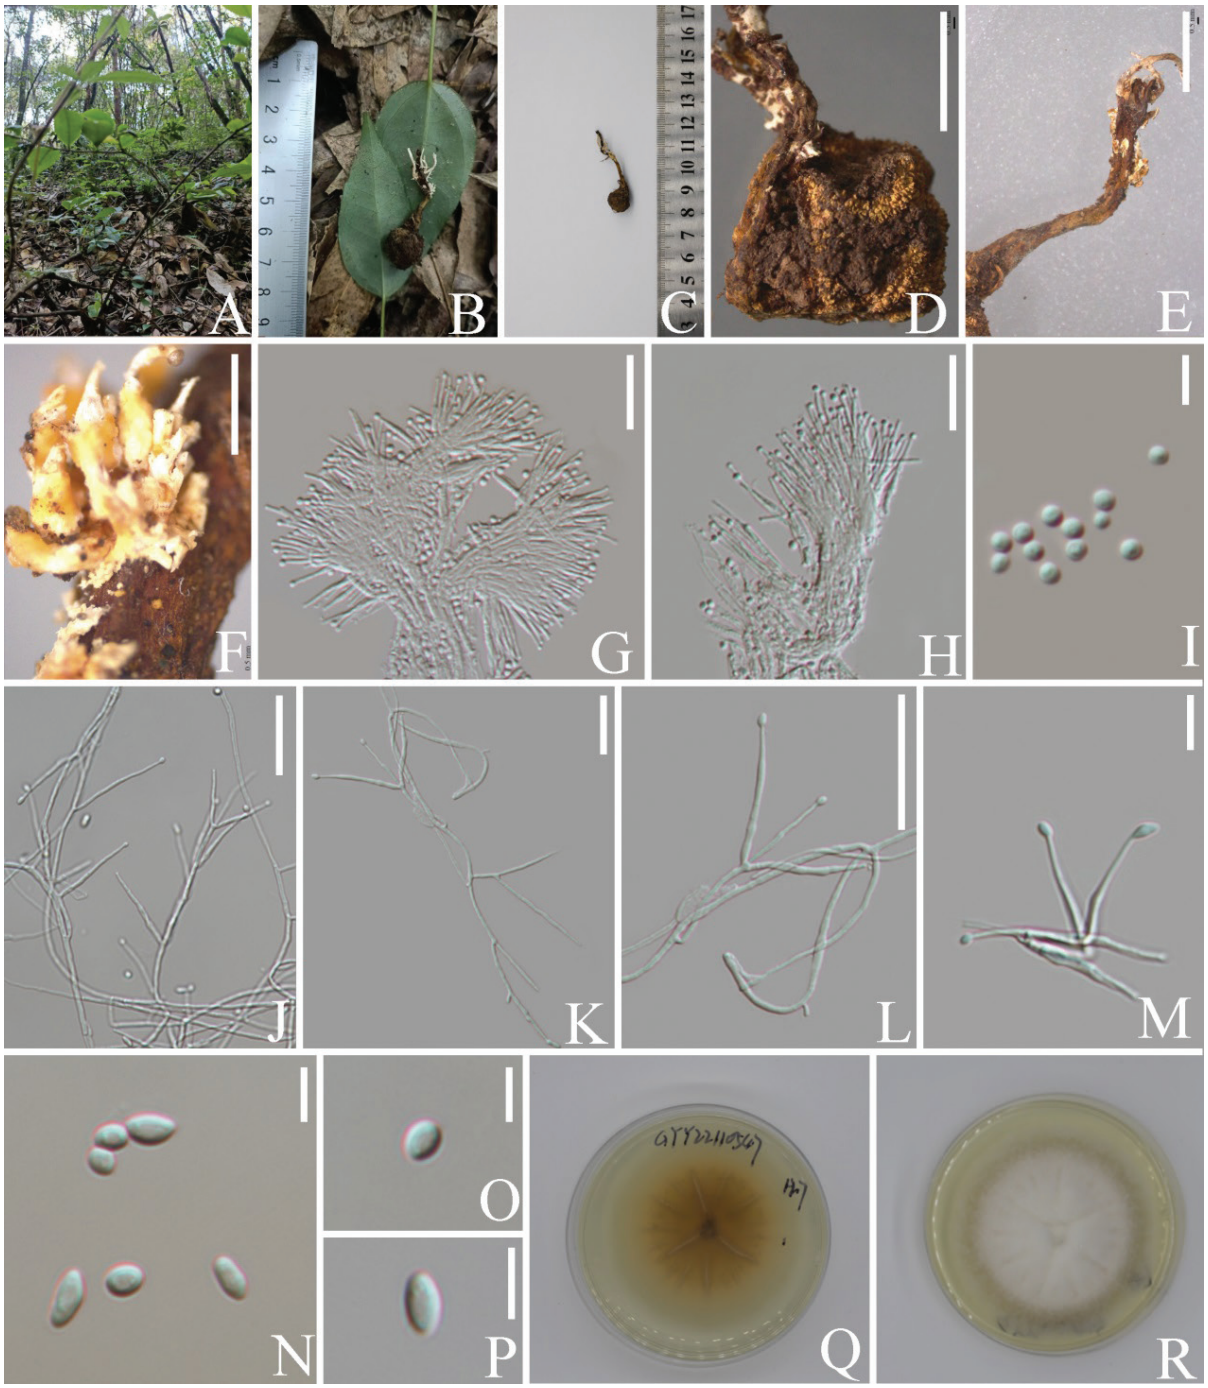

Figure 3. *Polycephalomyces tengchongensis* (**B–I** from HKAS 131923, **J–R** from KUNCC23-16073) **A** habitat **B–F** infected *Perennicordyceps* cf. *elaphomyceticola* showing synnemata of parasites **G, H** α-phialides **I** α-conidia **J–M** β-phialides **N–P** β-conidia **Q, R** reverse and front view of culture on PDA. Scale bars: 5 mm (**D–F**); 20 μm (**G, H**); 50 μm (**J–L**); 10 μm (**M**); 5 μm (**I, N–P**).

A comparison of nucleotide sequences between *Po. tengchongensis* and the ex-type of strain of *Po. formosus* (NBRC 109993) revealed 1% differences (6/584 bp) including three gaps in the ITS region, 0.3% (3/774 bp) differences including one gap in the LSU region, 2.3% differences (16/684 bp) including three gaps in the *rpb1* region and 1.6% differences (15/891bp) in the *rpb2* region. Collectively, the differences both in phenotypic profiles and nucleotides sequences support the establishment of *Polycephalomyces tengchongensis* as a new species.

Table 2. Morphological comparison between sexual species in *Paradingleyomyces*, *Perennicordyceps*, and *Dingleyomyces*.

Species	Host	Stromata (mm)	Perithecia (μm)	Asci (μm)	Apical cap (μm)	Secondary ascospores (μm)	References
Dingleyomyces lloydii	*Ophiocordyceps hauturu, Ophiocordyceps robertsii*	Reduced to white subiculum, flat, thin, irregular plates, often obscured by the perithecia, white or yellowish	300–950 × 300–650, superficial, ovoid, growing in small groups on white subiculum	200–450 × 6–10	2–3 diameter, 4 thickness	1.5–3 × 1–1.5	Dingley (1953); Mains (1958); Johnston and Park. (2023)
Perennicordyceps elaphomyceticola	*Elaphomyces* sp.	20–100 × 0.1–0.5, cylindrical, the colours vary from dark brown, titian red, brownish orange, yellow to pale	430–600 × 255–300, superficial, ovoid to ellipsoid, yellow when mature, pale when immature	365–420 × 5.0–7.6	2–3.5 × 3.3–5.2	1.5–3.2 × 1.4–2.3	Xiao et al. (2023)
Pe. cuboidea	Beetle larva or other *Cordyceps*	32–181 × 3–74, cylindrical, ochre yellow	400–500 × 250–330, superficial, lemon-shaped, glabrate	250–570 in length	3–5 in thickness	1.5–3 × 1–1.5	Ban et al. (2009)
Pe. prolifica	Cicada nymph	70.9–140.0× 0.8–2.2, thin cylindrical, brown	320–530 × 200–340, superficial, ovoid or ellipsoidal, grayish brown	430–650 in length	3–5 in thickness	2–3 × 1–2	Kobayasi and Shimizu (1963)
Pa. lepidopterorum	***Ophiocordyceps* cf. *cochlidiicola***	**Reduced to white subiculum**	**240–690 × 110–360, superficial, ovoid to ellipsoidal, brown**	**150–400 × 3–8**	**3–5 × 1–4**	**2–4 × 0.5–1**	**This study**
Pe. paracuboidea	Coleopteran larva	3.2–38.4 × 0.3–1.7, cylindrical	400–600 × 290–400, superficial, lemon-shaped, pale orangish brown	225–400 in length	3–6.3 in thickness	1.3–2.5 × 1–2	Ban et al. (2009)
Pe. ryogamiensis	Coleopteran larva	12–13 × 0.5, cylindrical, white, palely darkened, glabrate at the base	320–430 × 200–230, superficial, ovoid	450–610 in length	3.8–5 in thickness	2.5–5 × 1.5–2	Ban et al. (2009)

Pleurocordyceps parvicapitata **Y.P. Xiao, T.C. Wen & K.D. Hyde, in Xiao et al. Fungal Diversity 120: 50 (2023)**

Index Fungorum: IF559473

Figs 4, 5

Description. Parasitic on *Elaphomyces* sp. (Fig. 4). The host 6–10 mm in diam., dark brown or brown, spherical, hard, and rough on the surface. Sexual morph: ***Stromata*** 18–21 mm long, 1–2 mm wide, brown, multiple, fibrous. ***Stipe*** 8–15 mm long, 0.5–1 mm wide, brown, cylindrical, terminally or laterally carrying fertile cushions. ***Fertile cushions*** 0.5–1 mm in height, 1–2 mm in width, pale yellow to yellow, hemispherical. ***Perithecia*** 160–530 × 100–305 μm ($\bar{x}$ = 306 × 179 μm, n = 20), immersed, crowded, ovoid to obpyriform, ostiolate. ***Peridium*** 15–40 μm ($\bar{x}$ = 25 μm, n = 20) wide, three-layered, comprised of hyaline to pale yellow cells of ***textura intricate*** at outermost layer to ***textura angularis*** at middle layer to ***textura prismatica*** at inner layer. ***Asci*** 190–380 × 3–5 μm ($\bar{x}$ = 252 × 3.9 μm, n = 50), cylindrical, with thickened apex. ***Apical cap*** 1–2 × 2.5–4 μm ($\bar{x}$ = 1.7 × 3.4 μm, n = 60), hyaline. ***Ascospores*** filiform, multiseptate, hyaline, breaking into many secondary ascospores at maturity. ***Secondary ascospores*** 2–8 × 0.5–1 μm ($\bar{x}$ = 5.1 × 0.9 μm, n = 50), cylindrical, aseptate, straight, smooth-walled. Asexual morph: ***Synnemata*** cylindrical, off-white, gregarious, unbranched, occurring in close proximity to the fertile cushions. ***β-phialides*** up to 16 μm in length, 2 μm in width, cylindrical, attenuate toward the apex, phialidic, hyaline, smooth-walled. ***β-conidia*** 3–5 × 1–2 μm ($\bar{x}$ = 3.8 × 1.7 μm, n = 20), fusiform, hyaline, aseptate. Additionally, *Pleurocordyceps parvicapitata* parasitic on *Perennicordyceps elaphomyceticola* was found in proximity to the one on *Elaphomyces* sp. (Fig. 5). Sexual morph: ***Stromata*** not observed. ***Fertile cushion*** 0.5–1 mm long, 1–2 mm wide, directly growing on stromata of *Pe. elaphomyceticola*, pale yellow to yellow, surface wrinkle, rough due to the protruding perithecia. ***Perithecia*** 440–560 ×115–250 μm ($\bar{x}$ = 505 × 170 μm, n = 15) ovoid

to obpyriform, immersed, gregarious. ***Peridium*** 15–42 µm ($\bar{x}$ = 25 µm, n = 20) wide, three-layered, comprised of hyaline to pale yellow cells of ***textura intricate*** at outermost layer to ***textura angularis*** at middle layer to ***textura prismatica*** at inner layer. Asci and ascospores were not observed due to the specimen being immature.

Culture characters. Colonies isolated from *Elaphomyces* sp. and *Perennicordyceps elaphomyceticola* present similar characteristics. Colonies on PDA

attaining 41–45 mm in diam. after incubation at 25 °C for 14 days, white, leathery, reverse grayish yellow. ***Synnemata*** emerging from margin of colony in annular distributions, 1–3 mm long, 1–2.5 mm wide, white, erected, apically branched. ***Conidial mass*** gathers at middle part or tip of synnemata, pale yellow, waterish. ***Phialides*** two-typed. ***α-phialides*** 10–28 × 1–2 μm ($\bar{x}$ = 15.7 × 1.5 μm, n = 50), hyaline, smooth-walled, subculate, caespitose, palisade-like. ***α-conidia*** 1–2 μm ($\bar{x}$ = 1.7 μm, n = 45), one-celled, hyaline, smooth-walled, globose. ***β-phialides*** 6–8 × 0.5–1 μm ($\bar{x}$ = 7.9 × 1.1 μm, n = 20), arising from hypha, solitary, lanceolate, hyaline, smooth-walled. ***β-conidia*** 2–6 × 1–2 μm ($\bar{x}$ = 3.8 × 0.8 μm, n = 35), fusiform, hyaline, aseptate, smooth-walled, asymmetrical.

Material examined. China • Yunnan Province, Tengchong County, Houqiao Town; 5 Nov. 2022; Collected by Yi Wang; Parasitic on *Elaphomyces* sp. buried in soil; GYY546 (HKAS 131924, living culture: KUNCC23-16075) • *ibid*; Parasitic on *Perennicordyceps elaphomyceticola*; 5 Nov. 2022; Collected by Yi Wang; GYY553 (HKAS 131925, living culture: KUNCC23-16074).

Notes. *Pleurocordyceps parvicapitata*, parasitic on *Elaphomyces* sp. and *Perennicordyceps elaphomyceticola*, was originally described by Xiao et al. (2023) based on specimens collected from Dadugang County, Xishuangbanna, Yunnan Province, China. The specimen associated with *Elaphomyces* sp. produces pale yellow to yellow, wrinkled fertile cushions that are laterally or terminally attached to stromata, along with cylindrical asci, filiform, disarticulating ascospores and cylindrical, smooth-walled secondary ascospores. In this study, we collected a specimen displaying the typical characteristics of *Pl. parvicapitata* from Tengchong County, Yunnan Province. Importantly, Xiao et al. (2023) described *Pl. parvicapitata* as having one type of phialides and conidia from dry specimen. In contrast, we examined the asexual morph from both our specimens and its pure culture, observing dimorphic phialides and conidia. Additionally, the specimen associated with *Perennicordyceps elaphomyceticola* was previously known only from its asexual morphs (Xiao et al. 2023), where the species was described as having pulvinate, yellowish conidiomata with one-type of phialides and conidia on the stromata of *Pe. elaphomyceticola*. In this study, we collected a sexual specimen from Tengchong County, Yunnan Province and its fertile cushion was similar to *Pl. parvicapitata* found on *Elaphomyces* sp. (Xiao et al. 2023). This is the first report of the sexual morph of *Pl. parvicapitata* on *Pe. elaphomyceticola*, which differs from previously described sexual morphs in that it directly forms a fertile cushion on the substrate. We have also supplemented this species with a pure culture which can be used for further research. These findings provide deeper insights into the morphological traits of *Pl. parvicapitata*.

Pleurocordyceps yunnanensis **(Hong Yu bis, Y.B. Wang & Y.D. Dai) Y.H. Wang, S. Ban, W.J. Wang, Yi Li, Ke Wang, P.M. Kirk & Y.J. Yao, in Wang et al. Journal of Systematics and Evolution 59(5): 1076 (2021)**

Index Fungorum: IF570681

Fig. 6

Description. Parasitic on *Ophiocordyceps nutans* (Ophiocordycipitaceae, Hypocreales) (Fig. 6). Sexual morph: ***Stromata*** 12–25 mm long, 0.5–1 mm wide, fibrous, brown, multiple, unbranched. ***Stipes*** 5–11 mm long, ca. 0.5 mm wide,

Figure 6. *Pleurocordyceps yunnanensis* (HAKS 131922) **A** habitat **B–D** stromata of *Pl. yunnanensis* growing from the host (*Ophiocordyceps nutans*) **E** fertile head **F** cross-section through fertile head **G** perithecium **H** peridium **I–K** asci **L, M** part of asci **N** part of ascospore **O, P** secondary ascospores. Scale bars: 5 mm (**C, D**); 1 mm (**E**); 100 µm (**F, G**); 50 µm (**H–K**); 20 µm (**L, M**); 5 µm (**N–P**).

brown to pale brown. ***Fertile head*** 1–2.5 mm long, 0.7–1.3 mm wide, yellowish to yellow, capitate, rough. ***Perithecia*** 160–390 × 55–170 µm ($\bar{x}$ = 269 × 115 µm, n = 20), immersed, crowded, ovoid to obpyriform, ostiolate yellow, thick-walled. ***Peridium*** 14–46 µm ($\bar{x}$ = 32 µm, n = 25) wide, three-layered, comprised of hyaline to yellowish cells of ***textura prismatica*** at outer layer to ***textura angularis*** at middle layer to ***textura porrecta*** at inner layer. ***Asci*** 95–235 × 3–6 µm ($\bar{x}$ = 172 × 5 µm, n = 40), 8-spored, with thickened cap. ***Ascospores*** filiform, hyaline, multiseptate, disarticulating into many secondary ascospores at maturity. ***Secondary ascospores*** 2.5–5 × 1–2 µm ($\bar{x}$ = 3.9 × 1.3 µm, n = 40), cylindrical, aseptate, hyaline, smooth-walled. Asexual morphs: see Wang et al. (2015a).

Material examined. China • Yunnan Province, Kunming City, the Wild Duck Lake Forest Park; 17 Sep. 2023; Collected by Yi Wang; Parasitic on *Ophiocordyceps nutans*; YYH13 (HAKS 131922).

Notes. The asexual morph of *Polycephalomyces yunnanensis* was first described by Wang et al. (2015a) from *Ophiocordyceps nutans* in Wild Duck Lake Forest Park, Kunming, Yunnan Province. This species was later transferred to *Pleurocordyceps* by Wang et al. (2021) based on molecular phylogenetic analyses. In this study, a sexual polycephalomyces-like fungus growing on *O. nutans* was obtained from the same location as the type specimen (Fig. 6). Phylogenetic analysis revealed that it groups with strains of *Pleurocordyceps yunnanensis* with strong support (Fig. 1). Therefore, we introduce our specimen as the new sexual morph of *Pl. yunnanensis*.

Discussion

Polycephalomycetaceae was introduced by Xiao et al. (2023) to encompass the genera *Pleurocordyceps*, *Perennicordyceps*, and *Polycephalomyces*. The monophyletic nature of these three genera has been confirmed through numerous phylogenetic studies (Tian et al. 2010; Wang et al. 2012; Kepler et al. 2013; Wang et al.2015a; Zhong et al. 2016; Crous et al. 2017a; Sobczak etal. 2017; Poinar and Vega 2020; Xiao et al. 2018, 2023). Johnston and Park (2023) introduced a new genus, *Dingleyomyces*, into Polycephalomycetaceae. *Dingleyomyces* is a monotypic genus, and typified by *Dingleyomyces lloydii*, a species that is hyperparasitic on *Ophiocordyceps hauturu* from New Zealand. *Dingleyomyces lloydii* was placed in a distant clade branching off from *Perennicordyceps* (Johnston and Park 2023). In this study, we introduce a new genus, *Paradingleyomyces* to accommodate *Pa. lepidopterorum* which forms a distinct clade nested between *Perennicordyceps* and *Dingleyomyces* (Fig. 1).

Perennicordyceps currently comprises six species, four identified based on their sexual morphology and two based on their asexual morphology. We have compared the sexual characteristics of *Pa. lepidopterorum* with the four sexual species of *Perennicordyceps*, as depicted in Fig. 7. Several distinctions between *Paradingleyomyces* and *Perennicordyceps* are observed: 1) *Pa. lepidopterorum* is characterized by the absence of stromata, while *Perennicordyceps* species exhibit branched, cylindrical to clavate, rhizomorphic stromata; 2) The host of *Pa. lepidopterorum* is *Ophiocordyceps* cf. *cochlidiicola*, whereas *Perennicordyceps* parasitize a broader range of host, including insect and fungi; 3) The perithecia of *Pa. lepidopterorum* form on a white subiculum and are distributed over the entire stromata of the host fungus, while in *Perennicordyceps* species,

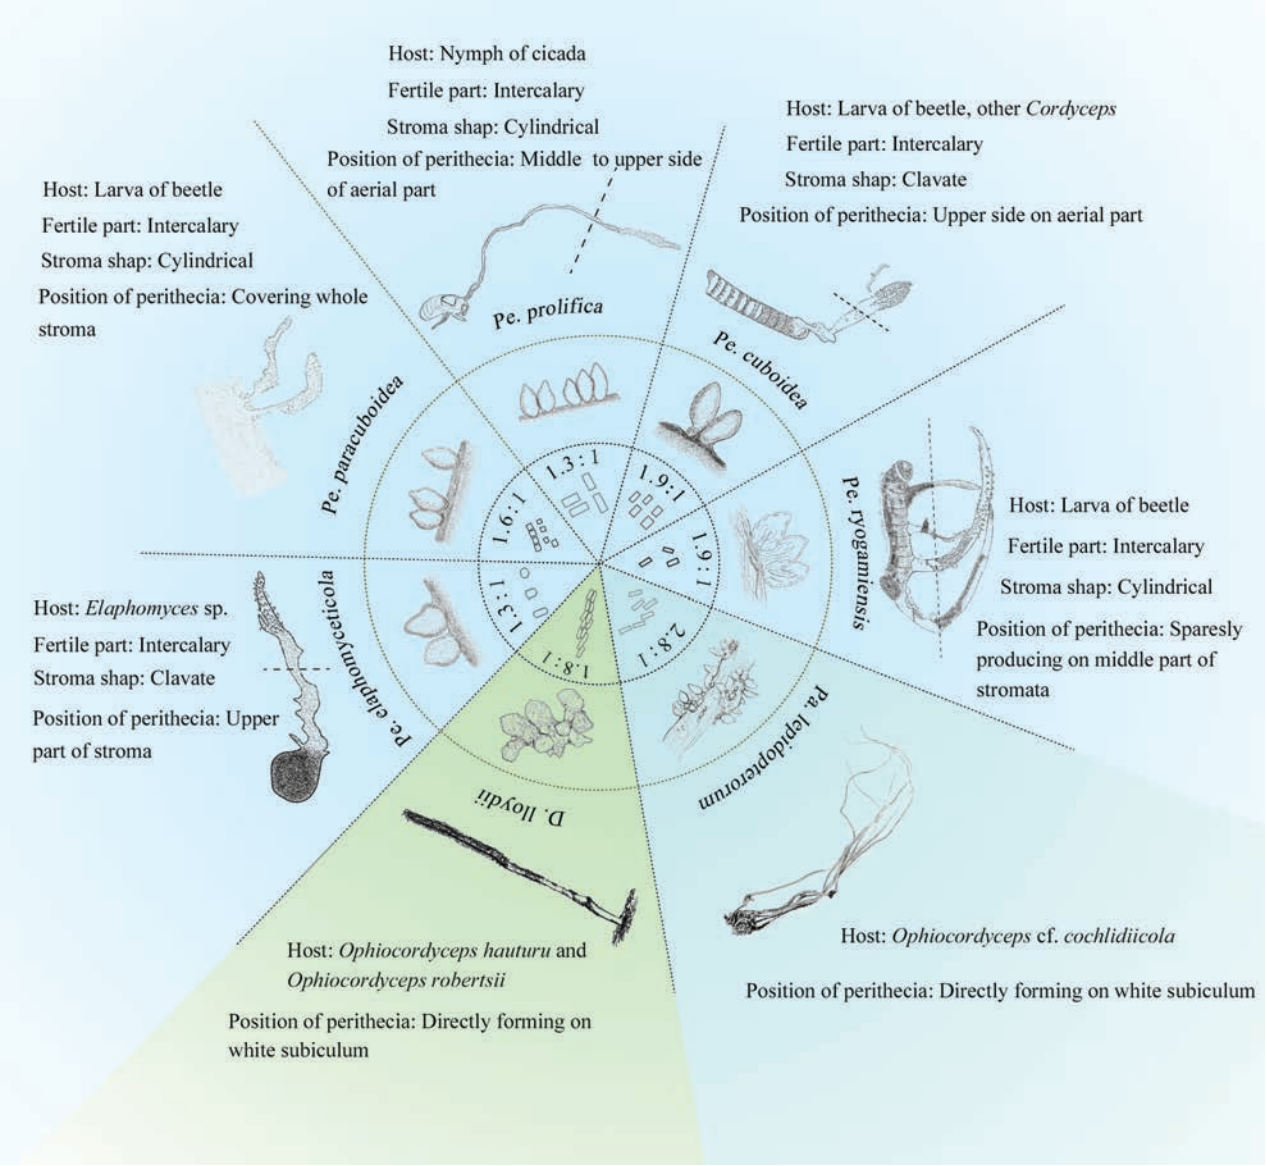

Figure 7. Morphological comparison of *Paradingleyomyces*, *Dingleyomyces* and *Perennicordyceps*. In *Perennicordyceps*, the dotted line below indicates burial in soil or woods. *Pe. cuboidea*, *Pe. prolifica*, *Pe. paracuboidea* and *Pe. ryogamiensis* were redrawn from Ban et al. (2009) and *Pe. elaphomyceticola* was redrawn from Xiao et al. (2023). *Pa. lepidopterorum* is a newly described species in this study. *D. lloydii* was redrawn from Johnston and Park (2023).

perithecia are densely formed from the middle to the upper part of the stromata; 4) The length-to-width ratio of secondary ascospores in *Pa. lepidopterorum* is 2.8: 1, which is greater than that observed in *Perennicordyceps* species. Consequently, we introduced *Paradingleyomyces* as a distinct genus rather than categorizing it within *Perennicordyceps*. Although *Dingleyomyces* has shares the poorly developed stromata connecting crowed perithecia to the stromata of *Ophiocordyceps hauturu* and *Ophiocordyceps robertsii*, giving a similar appearance to *Pa. lepidopterorum*, multigene phylogeny revealed a paraphyletic relationship between *Dingleyomyces* and *Paradingleyomyces*. Therefore, the establishment of *Paradingleyomyces* is well-supported by both morphological observations and phylogenetic analysis. The asexual morph of *Paradingleyomyces* is currently unknown, and future efforts should focus on exploring more hidden species within this genus.

Polycephalomyces was initially classified under Hypocreales *incertae sedis* (Kepler et al. 2013; Matočec et al. 2014). Up to 25 species were assigned to *Polycephalomyces*, but later some were transferred to *Pleurocordyceps* and *Perennicordyceps*, remaining eight species: *Po. albiramus*, *Po. formosus*, *Po. ramosus*, *Po. tomentosus*, *Po. baltica*, *Po. cylindrosporus*, *Po. ditmarii*, and *Po. paludosus* (Xiao et al. 2023). However, the phylogenetic relationships of the latter four species remain unclear due to a lack of molecular data. Notably, *Po. ramosus* and *Po. tomentosus* group with species of *Pleurocordyceps* in the study of Xiao et al. (2023) and this phylogenetic relationship is also observed in our study. Thus, the taxonomic status of *Po. ramosus* and *Po. tomentosus* remains questionable. In this study, we introduce a new species, *Polycephalomyces tengchongensis*, which is parasitic on *Perennicordyceps* cf. *elaphomyceticola* from Tengchong County, Yunnan Province, China. This new species is distinguished by a unique combination of features, including its host association, synnemata lacking a stipe and fertile head, and the presence of dimorphic phialides and conidia (see Table 3). The finding of *Po. tengchongensis* adds to the morphological diversity within the genus *Polycephalomyces*.

Pleurocordyceps was introduced by Wang et al. (2021) to accommodate ten species: *Pleurocordyceps agarica*, *Pl. aurantiacus*, *Pl. lianzhouensis*, *Pl. marginaliradians*, *Pl. nipponica*, *Pl. onorei*, *Pl. phaothaiensis*, *Pl. ramosopulvinatus*, *Pl. sinensis*, and *Pl. yunnanensis*, based on phylogenetic analysis. Wei et al. (2022) added a new species *Pleurocordyceps ophiocordycipiticola* which parasitizes *Ophiocordyceps cylindrospora* in Thailand. Xiao et al. (2023) introduced five additional species to this genus, including *Pl. heilongtanensis*, *Pl. lanceolata*, *Pl. nutantis*, *Pl. parvicapitata* and *Pl. vitellina*. Currently, *Pleurocordyceps* comprises 16 species, all of which have been verified by molecular phylogeny. The sexual morph of *Pleurocordyceps* is characterized by stipitate, fibrous stromata that produce pale yellow to yellow fertile cushion either laterally or terminally, with immersed ostiolate perithecia, cy-

Table 3. Distinguishing characteristics between *Po. tengchongensis* and other *Polycephalomyces* species.

Species	Host	Synnemata	Phialides (μm)	Conidia (μm)	Reference
Po. tengchongensis	***Perennicordyceps* cf. *elaphomyceticola* (Hypocreales, Polycephalomycetaceae)**	**Non-stipitate, without fertile head**	**Two-type, α-phialides 9–20 × 1–2, subulate; β-phialides 18–44 × 1–3, lanceolate**	**Two-type, α-conidia 1–3, globose; β-conidia 3–7 × 1.5–3, ellipsoidal to broadly fusiform**	**This study**
Po. albiramus	*Gryllotalpa* sp. (Orthoptera)	Stipitate, without fertile head	One-type, 12.8–18.3 × 1–2.2, narrowly subulate, awl-shaped	One-type 2.1–3.2 × 0.9–1.2, cylindrical to obovoid or subglobose	Xiao et al. (2023)
Po. baltica	Nymph or short-winged female bark louse	Stipitate, with fertile head	One-type, 3–4 long, flask-shaped	One-type, 3–4, globose	Poinar and Vega (2020)
Po. cylindrosporus	Coleoptera, Formicidae and Pentatomidae	Stipitate, with fertile head	One-type, 7–25 long	One-type, 2.5–4, cylindrical to bacilliform	Matočec et al. (2014)
Po. ditmarii	*Paravespula vulgaris* (Wasp), fly	Stipitate, with fertile head	One-type, 20–37 × 1.5–2.5, elongate, cylindrical, attenuating at the apex	One-type, 2.2–3 × 1.3–1.6, globose to subglobose to clavate	Van Vooren and Audibert (2005), Xiao et al. (2023)
Po. formosus	Coleopteran larvae or *Ophiocordyceps barnesii*	Stipitate, with fertile head	One-type, 6–25 × 1–1.2, cylindrical, tapering gradually	One-type, 2.5–3.2 × 1–1.2, ellipsoidal or ovoid	Kobayasi (1941)
Po. ramosus	Lepidopteran larvae or *Hirsutella guignardii*	Stipitate, with fertile head	Two-type, α-phialides 7–24 long, 1–2 at basal wide, cylindrical to narrowly lageniform; β-phialides 6–27 long, 2–3.5 at basal wide, 0.5–1 at neck width, narrowly lageniform or subulate	Two-type, α-conidia 2.4–3.2 × 1.6–2.4, ovoid; β-conidia 3.2–4 × 1.6–2, fusiform	Seifert (1985), Bischof et al. (2003)
Po. paludosus	Lepidopteran larva	Stipitate, with fertile head	One-type, 2–20 long, 1–1.5 at basal wide, subulate	One-type, 8–2.5 × 1.1–1.3, obovoid	Mains (1948)
Po. tomentosus	Myxomycetes	–	–	Three-type, globose or ellipsoidal or cylindrical	Seifert (1985)

lindrical asci, filiform disarticulating ascospores and cylindrical secondary ascospores. The asexual morph is characterized by stipitate, non-stipitate, or pulvinate synnemata, with or without fertile heads, generally displaying dimorphic phialides and conidia. Sexual morphs have been identified in six species including *Pl. marginaliradians* (Xiao et al. 2018), *Pl. nipponica*, *Pl. onorei* (Crous et al. 2017a), *Pl. parvicapitata* (Xiao et al. 2023), *Pl. phaothaiensis* (Crous et al. 2017b) and *Pl. ramosopulvinata* (Wang et al. 2021). The remaining 10 species of *Pleurocordyceps* have been described based on their asexual morphs. In this study, we report the sexual morph of *Pl. yunnanensis* from *Ophiocordyceps nutans* for the first time, collected from the same location as the type specimen. Ecologically, *Pleurocordyceps* species are particularly prone to infecting *Ophiocordyceps* or *Perennicordyceps* species, as well as their insect or fungal hosts. For instance, *Pl. parvicapitata* is known to infect *Perennicordyceps elaphomyceticola* and its host *Elaphomyces* sp. at the same region (Xiao et al. 2023). In this study, we once again obtained *Pl. parvicapitata* which infects both *Pe. elaphomyceticola* and its host *Elaphomyces* sp. from Tengchong County, Yunnan Province. This finding indicates that *Pl. parvicapitata* may be specific to *Pe. elaphomyceticola* and *Elaphomyces* sp. Additionally, we are the first to isolate and observe dimorphic phialides and conidia in *Pl. parvicapitata*, while Xiao et al. (2023) reported only one type of phialides and conidia from dried specimen. Therefore, the presence of dimorphs phialides and conidia should not be considered a reliable feature for species demarcation within *Pleurocordyceps*.

Abstract

Laurus nobilis is an important Mediterranean tree and shrub native to Italy that is also commercially grown as spice and ornamental plant. Field surveys conducted since 2021 in Sicily (Italy) revealed that bay laurel plants in urban and private gardens and nurseries were severely affected by symptoms of stem blight and internal necrosis, which were associated with ambrosia beetle entry holes in the bark and internal wood galleries. The occurring ambrosia beetle was identified as *Xylosandrus compactus*, an invasive wood-boring pest previously reported from Sicily. Investigation of fungi from symptomatic tissues primarily resulted in the isolation of *Thyridium*-like colonies. The main symbiont of *X. compactus*, *Ambrosiella xylebori*, was also isolated from infested plants. Phylogenetic analyses of a combined matrix of ITS, LSU, *act1*, *rpb2*, *tef1*, and *tub2* gene regions revealed that the isolated *Thyridium*-like colonies represent a new fungal species within the genus *Thyridium*. Based on both phylogeny and morphology, the new isolated fungus is described as *Thyridium lauri* **sp. nov.** Moreover, two recently described species, *Phialemoniopsis hipposidericola* and *Phialemoniopsis xishuangbannaensis*, are transferred to the genus *Thyridium* due to the confirmed synonymy of both genera, as supported by molecular phylogenies. Pathogenicity test conducted on potted plants demonstrated that *T. lauri* is pathogenic to bay laurel, causing internal necrosis and stem blight. The new species was consistently re-isolated from the symptomatic tissue beyond the inoculation point, thereby fulfilling Koch's postulates. This study represents the first report of a new pathogenic fungus, *T. lauri*, causing stem blight and internal necrosis of bay laurel plants and associated with infestation of the invasive ambrosia beetle *X. compactus*.

Key words: Fungal diseases, *Laurus nobilis*, phylogeny, stem blight and internal necrosis, taxonomy, *Xylosandrus compactus*

Introduction

Lauraceae is one of the largest families of trees and shrubs, distributed worldwide with approximately 55 genera and 3,000 species (Renner 2011; Zhang et al. 2023). This family includes economically important plants such as avocado (*Persea americana* Mill.), camphor (*Cinnamomum camphora* (L.) Sieb.), cinnamon (*Cinnamomum zeylanicum* Blume), and bay laurel (*Laurus nobilis* L.). Bay laurel,

also commonly known as sweet bay, is an evergreen tree or shrub naturally widespread across many countries of the Mediterranean basin, along the Atlantic coast of the Iberian Peninsula and the southern coast of the Black Sea (Giacobbe 1939; Rodríguez-Sánchez and Arroyo 2008). This plant is also cultivated in warm regions of the Americas, Eastern Asia, the Balkans, and Asia Minor (Batool et al. 2020; Singletary 2021). The economic importance of bay laurel lies in its use in public and private gardens as an ornamental tree or hedging plant (Raviv et al. 1982; Malaspina et al. 2022), as well as in its aromatic leaves, which serve as an important spice and flavoring agent in the culinary and food industries worldwide (Stefanaki and van Andel 2021). Traditionally, bay laurel leaves have been used in medicine by local people of Mediterranean countries for their biological properties, which are positively correlated with human health (Fang et al. 2005; Motti and de Falco 2021). Several recent studies have reported interest in the production of bay laurel plants due to the pharmacological and cosmetic properties of their essential oils and extracts (Lubbe and Verpoorte 2011; Ordoudi et al. 2022). Although bay laurel is investigated worldwide for its diverse potential uses, there is limited data available on fungal diseases affecting this plant. In Italy, leaf spots and stem blight caused by *Pestalotiopsis uvicola* (Speg.) Bissett, as well as crown and root rot caused by *Calonectria ilicicola* Boedijn & Reitsma have been reported on young potted plants (Vitale and Polizzi 2005; Polizzi et al. 2012). Furthermore, fungal diseases transmitted by bark and ambrosia beetles may pose a significant limitation to the cultivation of bay laurel on a global scale. Fungi closely associated with bark and ambrosia beetles are capable of infecting both the bark and wood tissues, resulting in severe diseases in the host tree. Among the fungi carried by these beetles, a quarantine pathogen is *Harringtonia lauricola* (T.C. Harr., Fraedrich & Aghayeva) Z.W. de Beer & M. Procter (formerly *Raffaelea lauricola*) (Ascomycota, Ophiostomatales) which causes a lethal vascular disease known as laurel wilt. This disease affects numerous species in the Lauraceae family, including bay laurel (Mayfield et al. 2008; Hughes et al. 2014, 2017; Eaton et al. 2023). This fungus has rapidly spread across the United States vectored by several species of ambrosia beetles, particularly *Xyleborus glabratus* Eichhoff (Coleoptera: Curculionidae), commonly known as the redbay ambrosia beetle (Ploetz et al. 2017).

Fungal species of the genus *Geosmithia*, particularly *Geosmithia langdonii* M. Kolařík, Kubátová & Pažoutová, *G. pallida* (G. Sm.) M. Kolařík, Kubátová & Pažoutová, and *G. putterillii* (Thom) Pitt (Ascomycota, Hypocreales), have been reported to be vectored by *Liparthrum colchicum* Semenov (Coleoptera: Curculionidae: Scolytinae), a phloem-feeding bark beetle, and are associated with dried twigs of bay laurel in France (Jordal et al. 2004; Kolarík et al. 2004, 2007) and Italy (Benvenuti et al. 2021; Vitale et al. 2021). *Ambrosiella xylebori* Brader ex Arx & Hennebert (Ascomycota, Ceratocystidaceae), along with *Fusarium* spp. and *Bionectria* sp., were involved in necrosis of twigs and branches of bay laurel infested by the ambrosia beetle *Xylosandrus compactus* (Eichhoff) (Coleoptera: Curculionidae) (Vannini et al. 2017). This invasive wood-boring insect pest, native to subtropical and tropical Asia, has been introduced to various subtropical regions worldwide, with its first report in the Mediterranean region coming from Italy in 2011 (FITOLAB 2011; Francardi et al. 2017). Currently, *X. compactus* is regarded as an emerging pest affecting various trees and ornamental plants in Italy (Francardi et al. 2017; Vannini et al. 2017; Gugliuzzo et al. 2019a, 2019b; Contarini et al. 2020), and bay laurel is reported as one of the preferred host plants of this am-

brosia beetle in the Mediterranean regions (Francardi et al. 2012; Barnouin et al. 2020; Riba-Flinch et al. 2021; Hızal et al. 2023). In Sicily, heavy infestations by *X. compactus* have primarily been reported on carob (*Ceratonia siliqua* L.), with less severe occurrences on bay laurel (Gugliuzzo et al. 2019c, 2023a).

Since 2021, bay laurel plants showing infestations of wood-boring insects associated with stem blight and internal necrosis have been observed in different nurseries of Sicily during field samplings following disease detection by farmers. From 2022 to 2024, additional surveys and observations were conducted in collaboration with the Regional Phytosanitary Service (Sicily, Italy) in street and park shrubs, private gardens, and nurseries with mother plants for tree propagation located in the Catania and Syracuse provinces. In most cases, the survey conduction revealed stem blight and internal necrosis, and the decline or death of numerous bay laurel trees, consistently accompanied by insect entry holes in the bark and internal galleries. As many fungal species have been reported worldwide for causing stem blight and internal necrosis of bay laurel associated with severe infestations of bark or ambrosia beetles, the aims of this study were to: i) characterize the fungal species associated with stem blight and internal necrosis of bay laurel plants; ii) assess their potential pathogenicity on healthy bay laurel plants; iii) identify the insect species co-occurring with these fungal phytopathogens in the diseased plants.

Materials and methods

Sampling, fungal isolation and beetle identification

Field samplings were carried out in June 2021 at nurseries located in Giarre (37°41.81'N, 15°11.52'E) and Mascali (37°44.85'N, 15°12.25'E) (Catania, Italy). Stem sections from 25 bay laurel plants exhibiting symptoms of stem blight, internal necrosis, and beetle infestations were randomly collected. Samples were then placed in sterile plastic bags and transferred to the laboratory of Plant Pathology at the Department of Agriculture, Food and Environment, University of Catania, for fungal isolation and insect identification. In the laboratory, 180 small wood fragments were collected from the discoloured inner woody tissues surrounding the outer portions of the beetle-bored galleries, excluding the interior of the galleries, which are typically inhabited by beetle-specific fungal symbionts. This approach was taken to focus on isolating the fungal species responsible for causing the disease. Each fragment was then divided into subsections (5 × 5 × 5 mm), with priority given to areas where the necrotic lesions were actively progressing (terminal discolored part). The subsections were sterilized in a 1.2% sodium hypochlorite solution for 60 s, rinsed once in sterile distilled water for 60 s, and air-dried in a laminar-flow hood on sterile paper. The surface-sterilized wood pieces were placed onto potato dextrose agar (PDA, Lickson, Vicari, Italy), supplemented with 100 mg L^{-1} of streptomycin sulphate (Sigma-Aldrich, St. Louis, MO, USA) to prevent bacterial growth, and then incubated at 25 ± 1 °C for ten days. The isolation frequency was calculated according to the formula: $F = (N_f/N_{tot}) \times 100$, where F is the frequency of putative fungal pathogen, N_f is the number of wood subfragments from which a fungal colony of interest emerged, and N_{tot} is the total number of wood subfragments cultured on PDA. Colonies of interest were subcultured on PDA plates to obtain pure cultures for macro- and microscopic observations and DNA extraction.

Twelve representative colonies of the most frequently recovered fungus were selected to obtain single-spore isolates and were stored in the collection of the Department of Agriculture, Food and Environment, Plant Pathology Section, University of Catania, for further analyses. Several beetles were extracted from the infested laurel stem sections, individually placed into sterile vials, and transferred to the Section of Applied Entomology of the same Department for beetle species identification. All adult beetles were then observed under a stereomicroscope for morphological identification, following the keys provided by Rabaglia et al. (2006).

Morphological characterization of fungal species

Three representative isolates (ALF2, ALF6, and ALF11) were selected for the description of pure cultures and morphological characterization. Cultures were grown on potato dextrose agar (PDA) and on cornmeal agar (Sigma, St Louis Missouri), amended with 2% (w/v) D(+)-glucose-monohydrate (CMD) at room temperature and ambient light. Colony features, such as texture, obverse and reverse colour, margin, and zonation were recorded. To examine sporulating structures, microscope slides were prepared in 3% KOH and observed at 100 × magnifications using a Zeiss Axio Imager.A1 compound microscope (Oberkochen, Germany) equipped with a Zeiss Axiocam 506 colour digital camera. Specifically, the length and width of conidia, as well as the length and width of conidiogenous cells (phialides) at their base, were measured, and the length-to-width ratio of conidia was calculated. Measurements of conidia are reported as maxima and minima in parentheses and the mean plus and minus the standard deviation of several measurements given in parentheses.

Holotype isolate (ALF11) was used to assess the effect of the temperature on mycelial growth rate. The fungal isolate was grown on PDA at 25 ± 1 °C for 14 days in the dark. Mycelial plugs, 5 mm in diameter, were obtained from the margins of actively growing colonies using a sterile cork borer and placed in the center of Petri plates, containing PDA amended with 100 mg L^{-1} of streptomycin sulphate. The plates were incubated at 5, 10, 15, 20, 25, 30, 35 and 40 ± 1 °C for 14 days in darkness. Five Petri plates were used as replicates for each temperature. Two perpendicular diameters were measured using a scale ruler at 7 and 14 days post-inoculation.

The isolates used in this study are maintained in the culture collection of the Department of Agriculture, Food, and Environment, University of Catania. Moreover, three representative isolates (AL2, ALF6 and ALF11) were deposited at the Westerdijk Fungal Biodiversity Institute (CBS), Utrecht, the Netherlands. Dried sporulating cultures were deposited as voucher specimens in the fungarium of the Department of Botany and Biodiversity Research, University of Vienna (WU-MYC).

DNA extraction, PCR amplification and sequencing

Collected isolates were grown on PDA for 14 days for the genomic DNA extraction. Mycelium was scraped off and processed according to the manufacturer's protocol using the Wizard Genomic DNA Purification Kit® (Promega Corporation, Madison, WI, USA). DNA samples were stored at 4 °C until use.

The following loci were amplified and sequenced: the complete internally transcribed spacer region (ITS1-5.8S-ITS2) rDNA gene with primers ITS5 and ITS4 (White et al. 1990); an approximately 0.9 kb fragment of the large-subunit (LSU) ribosomal RNA gene with primers LR0R (Moncalvo et al. 1995) and LR5 (Vilgalys and Hester 1990); a ca. 0.9 kb fragment of the partial alpha-actin (*act1*) gene with primers Act-1 and Act-5ra (Voigt and Wöstemeyer 2000); a ca. 0.9 kb fragment of the DNA-directed RNA polymerase II second largest subunit (*rpb2*) gene with primers RPB2-5F2 (Sung et al. 2007) and fRPB2-7cr (Liu et al. 1999); a ca. 0.8 kb fragment of the translation elongation factor 1-alpha (*tef1*) gene with primers TEF1_INTF (Jaklitsch 2009) and TEF1-LLErev (Jaklitsch et al. 2005); a ca. 0.5 kb fragment of the *tef1* gene with primers EF-688F and EF-1251R (Carbone and Kohn 1999); a ca. 0.85 kb fragment of the beta tubulin (*tub2*) gene with primers tub-intF (5'-AACAAGTAYGTYCCTCGCGCCGT-3') and T22D (Voglmayr et al. 2019) and a ca. 0.4 kb fragment of the same gene with primers bt2a and bt2b (Glass and Donaldson 1995).

The PCR amplification products were estimated visually by electrophoresis on 1% agarose gels and subsequently purified using an enzymatic PCR cleanup (Werle et al. 1994), as described in Voglmayr and Jaklitsch (2008). PCR products were sequenced in both directions by Macrogen Inc. (Seoul, South Korea) or at the Department of Botany and Biodiversity Research, University of Vienna, using the ABI PRISM Big Dye Terminator Cycle Sequencing Ready Reaction Kit v. 3.1 (Applied Biosystems, Warrington, UK) and the same primers as in PCR. Sequencing was performed on an automated DNA sequencer (3730xl Genetic Analyser, Applied Biosystems). The DNA sequences generated were assembled with Lasergene SeqMan Pro (DNASTAR, Madison, WI, USA) and deposited in GenBank (https://www.ncbi.nlm.nih.gov/) (Table 1).

Phylogenetic analyses

The sequences obtained in this study were compared with NCBI GenBank nucleotide database using the standard nucleotide Basic Local Alignment Search Tool (BLAST) (https://blast.ncbi.nlm.nih.gov/Blast.cgi). All single-spore isolates (ALF1, ALF2, ALF3, ALF4, ALF5, ALF6, ALF8, ALF10, ALF11, ALF14, ALF17, ALF19) were used for phylogenetic analyses within a combined matrix of ITS rDNA, LSU, *act*, *rpb2*, *tef1*, and *tub2* sequences. The newly generated sequences of each genomic region were aligned to reference sequences of *Thyridium* downloaded from GenBank, with two species from the Annulatascales and one species of *Myrmecridium* (Myrmecridiales) selected as the outgroup. For *Thyridium*, 10 accepted species and two recently described species of *Phialemoniopsis* for which sequences were available were included in the matrix, including ex-epitype and ex-holotype strains. The GenBank accession numbers of the sequences used in these analyses are given in Table 1.

Sequence alignments for phylogenetic analyses were produced with the server version of MAFFT (https://mafft.cbrc.jp/alignment/server/) and checked and refined using BioEdit Sequence alignment Editor 7.7.1.0 (Hall 1999). All six loci (ITS, LSU, *act1*, *rpb2*, *tef1*, *tub2*) were concatenated to a combined matrix using Phyutility v. 2.2 (Smith and Dunn 2008). The combined data matrix for phylogenetic analyses contained 4257 characters (528 nucleotides of ITS, 816 nucleotides of LSU, 839 nucleotides of *act1*, 879 nucleo-

[a] Strains and sequences generated in this study are shown in bold.
[b] ET = epitype; HT = holotype.
[c] ITS, internal transcribed spacer; LSU, large-subunit ribosomal RNA gene; *act1*, the partial alpha-actin gene; *rpb2*, DNA-directed RNA polymerase II second largest subunit gene; *tef1*, translation elongation factor 1-α; *tub2*, beta-tubulin.

tides of *rpb2*, 785 nucleotides of *tef1*, and 410 nucleotides of *tub2*). Maximum likelihood (ML) analyses were performed with RAxML (Stamatakis 2006), as implemented in raxmlGUI 2.0 (Silvestro and Michalak 2012), using the ML + rapid bootstrap setting and the GTRGAMMA+I substitution model which was selected as the most appropriate model by Modeltest. The matrix was partitioned for the different gene regions, and bootstrap analyses were done with 1,000 bootstrap replicates. For evaluation and interpretation of bootstrap support, values between 70% and 90% were considered moderate, above 90% as high, and 100% as the maximum. Maximum parsimony (MP) bootstrap analyses were performed with Phylogenetic Analyses Using Parsimony (PAUP) v. 4.0a169 (Swofford 2002). A total of 1,000 bootstrap replicates were implemented using five rounds of heuristic search with random sequence addition, followed by tree-bisection-reconnection (TBR) branch swapping. The MULTREES option was enabled, the steepest descent option was disabled, the COLLAPSE command was set to MINBRLEN, and each replicate was limited to 1 million rearrangements. All molecular characters were treated as unordered and assigned equal weight, with gaps considered as missing data. The COLLAPSE command was set to MINBRLEN.

Pathogenicity test

To assess the pathogenicity of *T. lauri*, two-year-old potted bay laurel plants grown under controlled growth chamber conditions were used. The holotype isolate (ALF11) was grown on PDA amended with 100 mg L^{-1} of streptomycin sulphate and incubated at 25 ± 1 °C for 30 days. The stems were surfaced disinfected with a 70% ethanol solution, and the bark was gently scraped using a sterile blade. The mycelial plug was then placed upside down onto the wound. Wounds were sealed with Parafilm to prevent desiccation. All inoculated plants were moved to a growth chamber with a 12 h photoperiod and maintained at 25 ± 1 °C. The plants were regularly watered and monitored monthly for symptom development. A total of nine plants were inoculated with *T. lauri* ALF11, while the control group consisted of an equal number of plants inoculated with sterile PDA. After four months, the phloem tissue was peeled back, and the lesion length extending both upward and downward from each inoculation site was measured. The mean and standard deviation were calculated. Pieces of necrotic tissue were cultured as previously described to fulfill the Koch's postulates, and the frequency of *Thyridium*-like colonies was determined.

Results

Sampling, fungal isolation and beetle identification

In the surveyed nurseries, bay laurel plants consistently showed symptoms of stem blight. The initial external symptoms observed included blight of the terminal leaves, beginning at the tips and progressing downward along the twigs. The leaves became dry as though suffering from lack of water and remained attached to twigs for several months (Fig. 1). In the most severe cases, the entire tree died. Symptomatic plants consistently exhibited bark necrosis surrounding small, circular entry holes bored by beetles, with diameters ranging from approximately 0.7 to 0.9 mm (Fig. 2a). Upon removing the bark from symptomatic stems or twigs with beetle entry holes, black to brown streaks of discoloration were observed in the sapwood, extending from the entry points into the surrounding wood (Fig. 2b–d). Longitudinal sections of the stem revealed discoloration extending upwards and downwards from the beetle galleries. Disease incidence, based on the number of plants showing symptoms of stem blight associated with ambrosia beetle attack in the nurseries where the disease was first observed (Mascali), ranged from approximately 30% to 40% of the 3,000

Figure 1. Symptoms of stem blight on bay laurel plants in nurseries located in Catania province **A** stem blight of twigs on a four-year-old tree, typically observed on a section of the canopy **B** stem blight of the lower part of plant **C** stem discoloration progressing from the tips to the lower part of the twig (red arrow).

total plants. Two types of fungal colonies were consistently recovered from symptomatic tissue, with isolation frequencies ranging from 60 to 95% for *Thyridium*-like colonies and from 5 to 40% for *Ambrosiella*-like colonies. More than 300 adult beetle females were collected from diseased samples all of which were morphologically identified as *X. compactus*, the sole beetle species present in the sampled woody material.

Phylogenetic analyses and fungal species identification

Of the 4257 characters of the combined matrix used for phylogenetic analyses, 593 were parsimony informative (44 from ITS, 68 from LSU, 102 from *act1*, 259 from *rpb2*, 62 from *tef1*, and 51 from *tub2*), 364 were parsimony-uninformative and 3300 were constant. The ML tree (-lnL = 13574.613578) obtained by RAxML is shown in Fig. 3. Maximum Likelihood analyses resulted in a tree topology similar to that revealed by MP bootstrap analysis. The monophyly of the genus *Thyridium* was strongly supported, with 97% support in the ML analysis and 98% in the MP analysis, as was the monophyly of most *Thyridium* species included. However, the two non-type strains of *T. vestitum* (CBS 113027, CBS 125582) did not form a monophyletic clade, indicating that at least one of the two isolates is misidentified. The twelve isolates of this study formed a distinct monophyletic clade within *Thyridium*, representing a new species with maximum support. This clade was resolved as a sister group to a highly supported clade (96% ML, 95% MP) containing *T. curvatum*, *T. flavostromatum*, *T. hongkongense*, and *T. limonesiae*. While most terminal and basal nodes received high to maximum support, intermediate nodes were generally poorly supported.

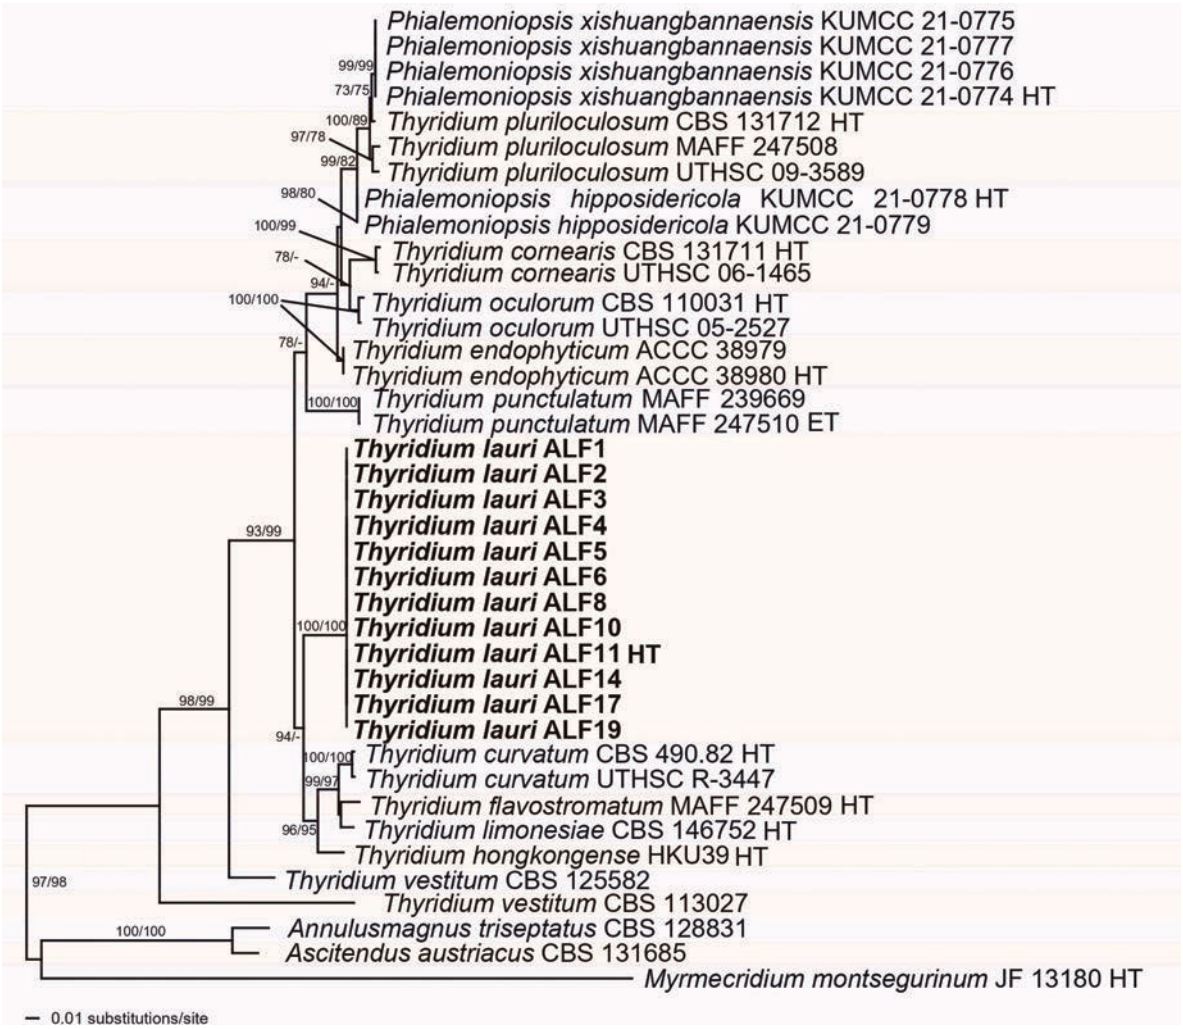

Figure 3. Phylogram of the best ML tree (-lnL = 13574.613578) revealed by RAxML from an analysis of the combined ITS-LSU-*act1-rpb2-tef1-tub2* matrix of *Thyridium*, showing the phylogenetic position of the new species from diseased *Laurus nobilis* (bold), with *Annulusmagnus triseptatus*, *Ascitendus austriacus* and *Myrmecridium montsegurinum* selected as outgroup to root the tree. Maximum Likelihood (ML) and Maximum Parsimony (MP) bootstrap support above 70% are given at first and second position, respectively, above or below the branches. ET = epitype; HT = holotype.

Pathogenicity test

The pathogenicity test confirmed that the new *Thyridium* species is pathogenic to bay laurel, causing internal necrosis and stem blight of all inoculated plants. The initial visible external symptoms included brown to black necrotic lesions at the inoculation site (Fig. 4), followed by the development of stem blight within four months. Internally, plants exhibited discoloration, characterized by brownish to blackish streaking in the sapwood, with a mean lesion length of 16.6 ± 7.1 cm. In addition, some inoculated and control plants exhibited brown exudates, which over time became crusty and adherent to the bark as a response to mechanical damage. Control plants displayed no internal symptoms, aside from minor wound oxidation. *Thyridium* was consistently re-isolated from necrotic tissue but was absent in the control treatments. The re-isolation frequency was 94%, and the emerging fungal colonies matched the originally inoculated *Thyridium* isolates based on morphological observations of the colony and conidia. Therefore, Koch's postulates were fulfilled.

Figure 4. Pathogenicity test on bay laurel **A** stems inoculated with *Thyridium lauri* isolate ALF11, showing symptoms of external lesion **B** internal necrosis with brownish to blackish streaking in the sapwood **C** control plant inoculated with sterile PDA.

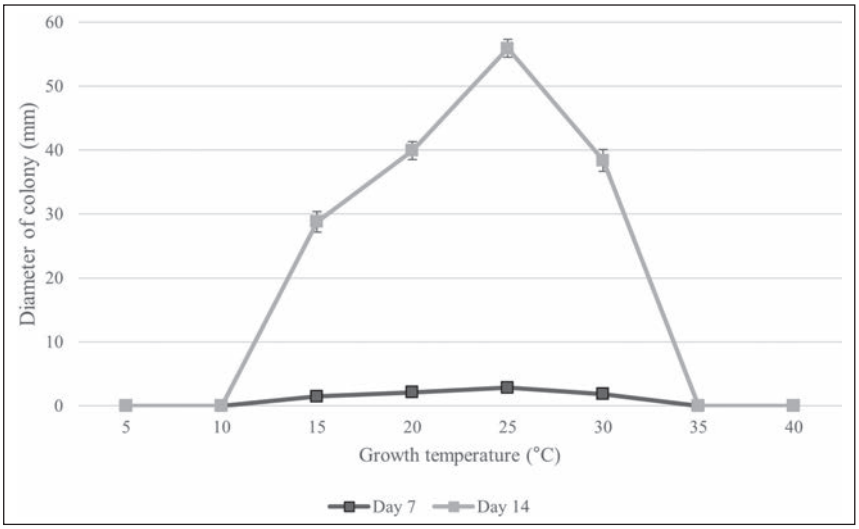

Figure 5. Effect of temperature on mycelial growth rate of *Thyridium lauri* ALF11 isolated from bay laurel. Data are means of five replicated Petri plates with bars indicating the standard error (SE).

Growth rate experiments

The growth rate experiments of *T. lauri* isolate ALF11 are shown in Fig. 5. The fungus grew slowly at 15 °C (29 mm diameter after 14 days). No mycelial growth was observed at 0, 5, 10, 35, and 40 °C while optimal growth occurred within the temperature range of 20 to 30 °C.

Taxonomy

***Thyridium lauri* Voglmayr, D. Aiello & G.R. Leonardi, sp. nov.**
MycoBank No: 854792
Figs 6, 7

Etymology. Referring to its host, *Laurus nobilis*.

Type. Italy • Sicily, Catania province, plant nursery located in Mascali, 37°44.85'N, 15°12.25'E, isolated from diseased corticated twigs of *Laurus nobilis*, 23 June 2021, G. Polizzi (holotype WU-MYC 0052725 dried culture; ex-holotype culture ALF11 = CBS 151898).

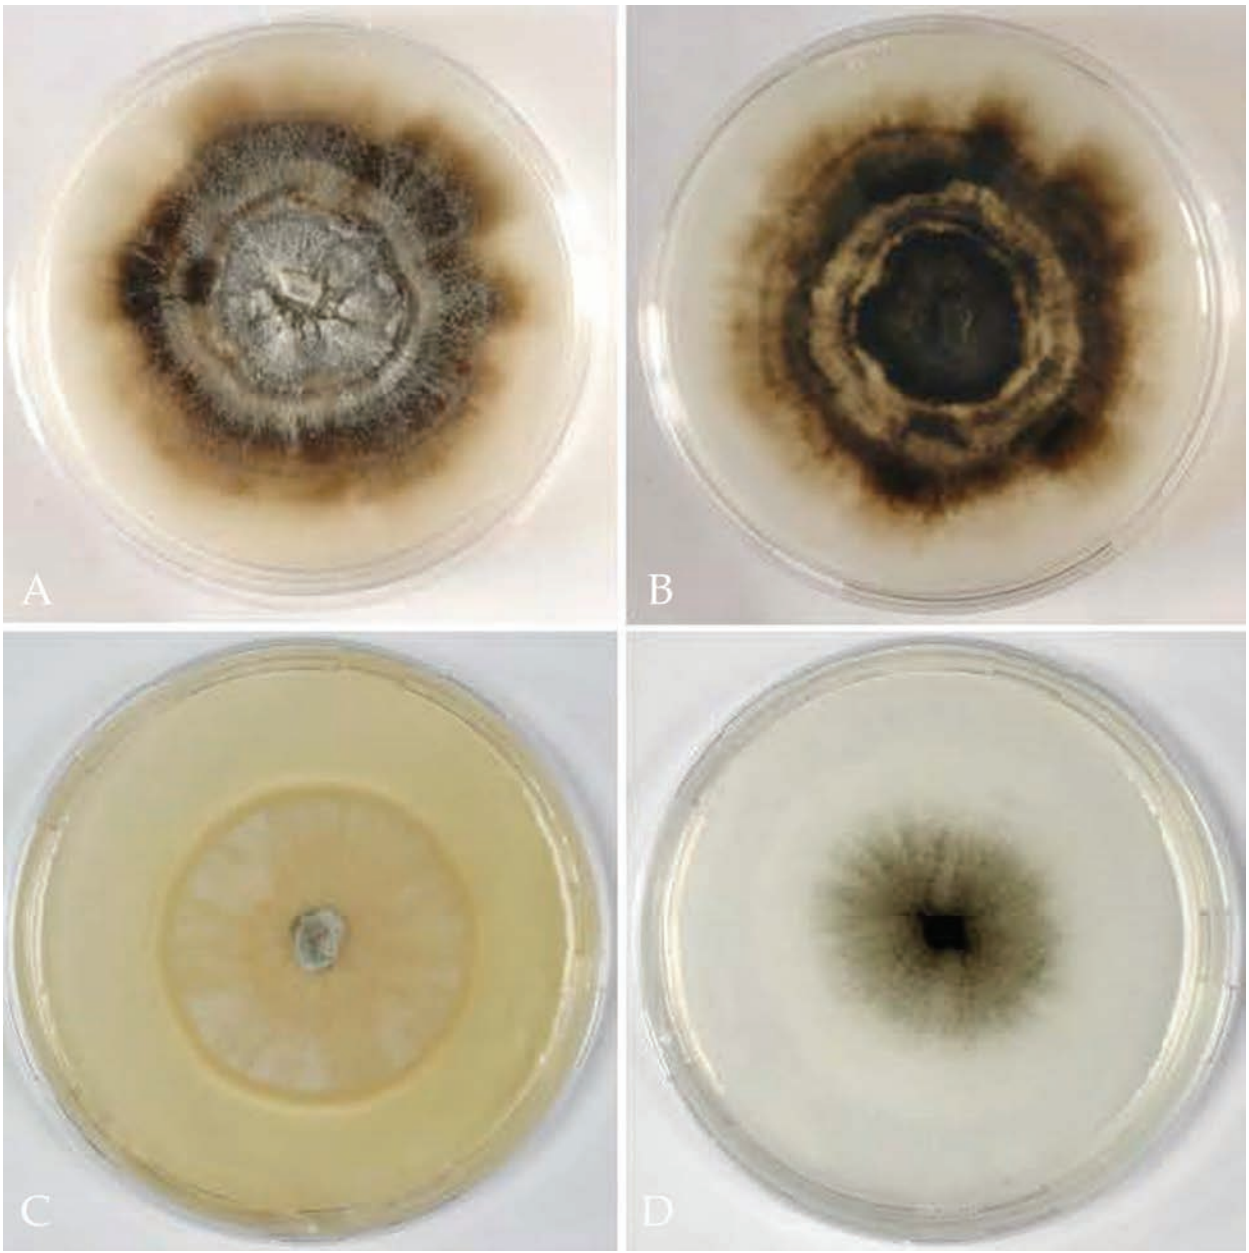

Figure 6. Colonies of *Thyridium lauri* (ALF 11, ex-holotype culture) **A** on PDA (1 month, 22 °C) **B** on PDA (1 month, 22 °C), reverse **C** on ½ PDA (21 days, 22 °C) **D** on CMD (21 days, 22 °C).

Description. On PDA reaching 54–56 mm diameter after 21 days, first pale creamy to yellowish, cottony in the centre, with dense whitish aerial mycelium after 14 days, after 1 month colonies ochraceous to umber brown in the centre, with distinct concentric lighter and darker zones, aerial mycelium white or grayish in the centre, sparse or lacking towards the margins, forming dry effused patches of branched aerial conidiophores interspersed with spot-like to effused patches of densely branched conidiophores immersed in white to cream slimy conidial masses; reverse dark umber brown in the centre, with lighter and darker brown concentric zones towards the margins. On CMD reaching 59–62 mm diameter after 21 days, colonies first whitish, from the centre becoming greenish brown with age, finally blackish brown in the centre, aerial mycelium sparse to absent, with scant erect branched conidiophores and strands of aggregated radial hyphae on the agar surface. Sporodochia and pycnidia not observed. Conidiation of three types, all of (sub)hyaline, thin-walled cells: (1) on tufts of aerial, several times loosely branched conidiophores, with straight elongate hyphal conidiophore cells and cylindrical to narrowly-ampulliform terminal or lateral conidiogenous cells (phialides) of variable length up to 50 µm long, producing conidia terminally; (2) on densely branched, interwoven-aggregated conidiophores, with knobby to sinuous conidiophore cells and terminal or lateral conidiogenous cells (polyphialides) of variable, irregular flexuous-knobby shape, 4–18 × 1.2–3.6 µm (n = 155), forming conidia terminally and/or laterally; and (3) on straight to bent adelophialides formed singly on hyphae at more or less right angles, 1–13 × 0.7–1.8 µm (n = 56), with a tiny pericline apical thickening, but without visible collarettes. Conidia hyaline to subhyaline, thin-walled, of two types: (1) subglobose to broadly ellipsoid, uni- to irregularly multiguttulate, commonly aggregated in spot-like to effuse slimy masses, produced on the branched conidiophore type (2), (2.2–)3.0–3.8(–4.8) × (2.0–)2.3–3.0(–3.7) µm, l/w = (1.0–)1.2–1.5(–1.9) (n = 211); (2) elongate, ellipsoid to allantoid, mostly biguttulate with a guttule near each end, mainly borne from adelophialides but also on conidiophore type (1), (2.3–)3.0–4.0(–4.9) × (1–)1.3–2.0(–2.8) µm, l/w = (1.2–)1.8–2.8(–4.0) (n = 169). Subglobose to broadly ellipsoid conidia mainly produced in masses on PDA in older parts of the colony; elongate to allantoid conidia commonly observed on CMD, more rarely on PDA, produced within 3–4 days mainly in the actively growing younger parts of the colony. On inoculation plugs of PDA cultures placed on CMD yeast-like cells observed 3 to 4 days after inoculation, developing by budding at one or two ends from swollen subglobose conidia. Sexual morph unknown.

Additional specimens examined. Italy • Sicily, Catania province, plant nursery located in Giarre, 37°41.81'N, 15°11.52'E, isolated from twig necrosis of *Laurus nobilis*, 10 June 2021, G. Polizzi (WU-MYC 0052726, dried culture ALF2; CBS 151896); • Catania province, plant nursery located in Giarre, 37°41.81'N, 15°11.52'E, isolated from twig necrosis of *Laurus nobilis*, 10 June 2021, G. Polizzi (WU-MYC 0052727, dried culture ALF6; CBS 151897).

Based on the results of molecular phylogenies (Fig. 3) and the synonymy of *Phialemoniopsis* with *Thyridium* two recently described *Phialemoniopsis* species are here combined in *Thyridium*.

Discussion

This study revealed stem blight of bay laurel in Southern Italy as being associated with a new fungal species within the genus *Thyridium* (Sordariomycetes, Thyridiaceae). The isolates obtained from symptomatic tissues were identified based on the morphological characteristics and molecular phylogenetic analyses of the ITS, LSU, *act1*, *rpb2*, *tef1*, and *tub2* gene regions. Recently, Sugita and Tanaka (2022) provided a phylogenetic treatise on the genus *Thyridium*, which included the same six loci sequenced in our study. Molecular evidence and morphological similarities in the asexual morph revealed that the anamorph genus *Phialemoniopsis* is congeneric with *Thyridium*, leading to the reclassification of eight *Phialemoniopsis* species into *Thyridium* (Sugita and Tanaka 2022). Currently, molecular data for 10 *Thyridium* species and 2 *Phialemoniopsis* species originating from different substrates, including humans, animals, and plants, are available in GenBank. According to Index Fungorum (https://www.indexfungorum.org/Names/Names.asp; Accessed April 19, 2024), a total of 65 *Thyridium* species have been described, of which 44 are currently recognised within the genus *Thyridium*. However, sequence data are not yet available for the majority of these species, with 34 lacking molecular information. Two species of *Phialemoniopsis*, *P. hipposidericola* and *P. xishuangbannaensis*, recently described from bats in Southern China (Liu et al. 2023), are also classified within *Thyridum* based on molecular phylogenies (Fig. 3) and are therefore combined in *Thyridium* in this study.

In this study, the sequenced isolates formed a clade that is significantly distinct from all known *Thyridium* species with available sequence data, and are therefore described as a new species, *T. lauri*. Our isolates are phylogenetically close to *T. curvatum*, *T. flavostromatum*, *T. hongkongense*, and *T. limonesiae*, which were recovered from parts of human body (Perdomo et al. 2013; Tsang et al. 2014) or associated with human infections (Perdomo et al. 2013; Alvarez Martinez et al. 2021). *Thyridium lauri* shares similar morphological characteristics with other *Thyridium* species, with only minimal distinct traits observed. Nevertheless, the newly proposed species does not produce pycnidium-like conidiomata or chlamydospores unlike many phialemoniopsis-like asexual morphs of *Thyridium*. Similarly, no pycnidium-like conidiomata or chlamydospores have been observed in *T. curvatum* (Perdomo et al. 2013), *T. hongkongense* (Tsang et al. 2014), and *T. limonesiae* (Alvarez Martinez et al. 2021). *Thyridium lauri*

is characterised by the production of subglobose conidia aggregated in slimy masses and of yeast-like cells developing by budding from the same type of conidia. Moreover, it can be morphologically distinguished from the other species of the sister clade. The new species is distinguished from *T. hongkongense* by its larger elongate, ellipsoid to allantoid conidia (2.3–4.9 × 1.3–2.8 µm), while conidia of *T. hongkongense* are small, cylindrical, oval or rod- shaped, and slightly curved (2–3 × 1–2 µm) (Tsang et al. 2014). Similarly, *T. limonesiae* produces shorter cylindrical or oval conidia (2.3–4.9 × 1.4–2 µm) (Alvarez Martinez et al. 2021). Although *T. lauri* appears quite similar to *T. curvatum* in producing two types of conidia, *T. curvatum* is distinguished by its longer allantoid conidia (4–6 × 1–2 µm), shorter ellipsoid to ovoid conidia (1–2 × 0.5–1), and the presence of sporodochial conidiomata which were not found in *T. lauri* or *T. flavostromatum* (Perdomo et al. 2013). Within this sister group, *T. flavostromatum* produces the longest ellipsoid to allantoid conidia (2–7 × 1–2.5 µm) (Sugita and Tanaka 2022), characterised by a slightly apiculate base. Unlike *T. lauri*, *T. flavostromatum* produces solitary clamydospores.

In addition to the morphological characteristics, *T. lauri* can be distinguished from other species by its notable ecological traits. The new species was isolated from two different locations in Sicily, from the same host, and was confirmed to be pathogenic to bay laurel, as demonstrated by our pathogenicity tests. Notably, several anamorphic *Thyridium* species have been reported as opportunistic human pathogens, including *T. curvatum*, *T. hongkongense*, *T. limonesiae*, *T. oculorum*, *T. pluriloculosum* (Gams and McGinnis 1983; Rivero et al. 2009; Desoubeaux et al. 2014; Tsang et al. 2014; Alvarez Martinez et al. 2021; Patolia and Bansal 2021). These species have also been isolated from various environments, including soil samples (*T. curvatum*) (Perdomo et al. 2013), diesel fuel tank (*T. curvatum*) (Varaljay et al. 2019), seawater samples (*T. pluriloculosum*) (Taha et al. 2021), and marine sediment (*T. oculorum*) (Mahanty et al. 2019). A few *Thyridium* species reported as human pathogens have also been isolated from plant material at different reproductive stages. For example, *T. pluriloculosum* originally found in human nails as an asexual fungus (Perdomo et al. 2013) and reported to cause human infections (Patolia and Bansal 2021), was later rediscovered in its sexual state on the twigs of *Betula maximowicziana* (Sugita and Tanaka 2022). Other *Thyridium* species were isolated from plants (*T. curvatum*, *T. endophyticum*, *T. flavostromatum*, *T. punctulatum*) as non-pathogenic endophytes or saprobes (Halleen et al. 2007; Kaur et al. 2014; Su et al. 2016; Sugita and Tanaka 2022). Among these, *T. curvatum* and *T. oculorum* were also isolated from asymptomatic nursery material and young grapevines affected by Petri disease, respectively, but their importance in the grapevine decline has not yet been confirmed (Halleen et al. 2007; Ferreira et al. 2018). It is important to note that several *Thyridium* species, yet to be sequenced, have been described as sexual morphs from dead plant tissues. A review of the literature reveals that a single species, *T. nobile*, was recorded from twigs of a member of Laureaceae, *Laurus novocanariensis* (Petrak 1929). According to the USDA Fungus-Host database (https://fungi.ars.usda.gov; Accessed April 19, 2024), *Thyridium* has been recorded neither from *Laurus nobilis* nor from other Lauraceae. We are therefore confident that our species has not yet been described. The observed morphological differences, combined with the phylogenetic analyses and ecological characteristics, support the classification of these isolates as a new species.

The pathogenicity tests on bay laurel demonstrated that *T. lauri* is responsible for causing necrotic lesions in the stems, ultimately leading to stem blight. However, *Xylosandrus compactus* may also play a significant role in the development of symptoms. Notably, during our surveys, the symptoms of stem blight observed in bay laurel were consistently associated with the presence of entry holes and galleries created by the adults of the invasive ambrosia beetle, *X. compactus*.

As reported by several authors, the tunnelling activity in the wood, which disrupts the transport of water and nutrients, along with the introduction of ambrosia fungi presumed to be pathogenic to the host trees, likely contributes to the severe stem blight or even death of the plants (Ngoan et al. 1976; Paine et al. 1997; Bosso et al. 2012; Pennacchio et al. 2012; Greco and Wright 2015). In 2011, *X. compactus* was first recorded for Europe (Garonna et al. 2012) in urban parks of the Campania region in Italy. In Sicily, this ambrosia beetle was mainly found infesting carob trees (Gugliuzzo et al. 2019a), while in other regions of Italy it has also been found infesting many other host plants, including bay laurel (Francardi et al. 2012; Bateman et al. 2016; Vannini et al. 2017). As the crucial role of arthropods in disease epidemiology has been increasingly recognized worldwide (Moyo et al. 2014; Cruz et al. 2021; Heitmann et al. 2021; Berasategui et al. 2022; Lunde et al. 2023), it cannot be excluded that the beetles may actively disseminate the fungal propagules, or alternatively provide entry points for secondary fungal infections (Brader 1964). However, specific investigations are needed to verify these hypotheses. Previous studies have demonstrated that *X. compactus* inhabits the xylem, where it introduces specific mutualistic symbiotic fungi on which it relies for nutrition. The most consistently associated symbiotic fungal species, isolated from *X. compactus* and its several hosts worldwide, were *Ambrosiella xylebori* Brader ex Arx & Hennebert, *A. macrospora* (Francke-Grosm.) L.R. Batra, and *Fusarium* spp. (Muthappa and Venkatasubbaiah 1981; Bhat and Sreedharan 1988; Bosso et al. 2012; Bateman et al. 2016; Gugliuzzo et al. 2020, 2021). In this study, *Ambrosiella*-like colonies were isolated from symptomatic woody tissues in addition to *T. lauri*. In contrast, previous investigations did not reveal the presence of *Thyridium* involved in stem blight and internal necrosis associated with *X. compactus* (Vannini et al. 2017; Gugliuzzo et al. 2020; Benvenuti et al. 2021; Morales-Rodríguez et al. 2021; Vitale et al. 2022). However, some unidentified *Phialemonium* sp. and *Phialemoniopsis* sp. isolates were recorded in previous studies evaluating the fungal communities of *X. compactus* in the United States (Bateman et al. 2016) and Italy (Gugliuzzo et al. 2020). The ITS sequence of *Phialemonium* isolate Hulcr5398 (KU961666) (Bateman et al. 2016) matched very closely with *T. oculorum* (previously *Phialemoniopsis ocularis*, OR760549, HG933293), with a percentage identity of 99.6% in the BLAST search results. Moreover, phylogenetic analyses of the *Phialemonium* sp. isolate in our multigene matrix revealed that it was nested within the *T. oculorum* clade (data not shown), confirming its placement within *Thyridium*, although phylogenetically distant from *T. lauri*. While *Phialemoniopsis* and *Phialemonium* share highly similar morphologies, they phylogenetically belong to two distinct families within Sordariomycetes, Thyridiaceae and Cephalothecaceae, respectively (Perdomo et al. 2013; Hongsanan et al. 2017; Davolos et al 2019). Isolates morphologically identified as *Phialemonium* may, in fact, represent *Phialemoniopsis*, which is now considered a synonym of *Thyridium* (Sugita and Tanaka 2022).

One interesting finding is that the ITS of *Phialemoniopsis* isolate 50 (ON520570) (Gugliuzzo et al. 2020) was identical to *Thyridium* sp. (PP683252), and it matched very closely with *Phialemoniopsis* sp. isolates V18210, V18211, V18170, V18171 (ON413722, ON413723, ON415520, ON415521) and *Acremonium* sp. isolates Hulcr5037 (KU961664) and PB_AG_03 (OQ513933), with percentage identity ranging from 99 to 99.44% in the BLAST search results. Furthermore, phylogenetic analyses of the *Phialemonium* and *Acremonium* isolates in our multigene matrix, for which ITS and three LSU sequences are available in GenBank, showed that these isolates were nested within the *T. lauri* clade with high support (data not shown). This strongly suggests that they are members of *Thyridium* and are presumably very closely related, if not the same species. The *Acremonium* isolates Hulcr5037 and PB_AG_03, isolated from *X. compactus* in the United States (Bateman et al. 2016) and from *X. germanus* in Germany (Gugliuzzo et al. 2023b), respectively, were also reported to be one of the most prevalent fungi isolated from these beetles. However, their characterisation was based solely on the ITS sequences (Bateman et al. 2016; Gugliuzzo et al. 2023b). The other *Phialemoniopsis* sequences in GenBank that are highly similar to our ITS sequences originated from an unpublished study on fungi associated with *X. compactus* in the USA (ON413722, ON413723) and China (ON415520, ON415521). These remarkable findings suggest that the association of *T. lauri* and closely related fungal species with the beetle could be more widespread and stable, rather than attributed to a recent acquisition by the beetle from another host in the same area or to a recent introduction from other countries. The misidentification of the fungi commonly isolated from *X. compactus* may be attributed to the fact that earlier studies relied solely on ITS sequences, which were the only data available at the time, and *T. lauri* had not yet been described. This study enhances our understanding of the *Thyridium-Xylosandrus* association, and future multi-locus analyses of *Phialemoniopsis* and *Acremonium* isolates are necessary to accurately distinguish these species.

Interestingly, we observed a yeast-like phase of *T. lauri* when subcultured on a new medium, especially on inoculation plugs during the initial growth of the colony. It is known that symbiotic fungi of ambrosia beetles have evolved in a phase that facilitates the dissemination through the insect (Cassar and Blackwell 1996; Nel et al. 2021; Mayers et al. 2022). Several studies have demonstrated that ambrosia fungi are dimorphic, exhibiting both a mycelial phase and a yeast-phase, also referred to as the sprout-cell phase (Batra 1967). Specifically, *Harringtonia lauricola*, *Ceratocystis lunata*, and *Raffaela promiscua* have been reported in association with *Xyleborus affinis*, *Xylosandrus crassiusculus*, and *Xyleborinus saxesenii*, respectively, undergoing the dimorphic transition from filamentous to yeast-like growth, which was also observed *in vitro* (Batra 1967; Nel et al. 2021; Mayers et al. 2022; Joseph et al. 2023). This finding suggests that the newly described species may have a predisposition for developing associations with arthropods. In conclusion, this study identified a new pathogenic fungal species, *Thyridium lauri* sp. nov., responsible for causing stem blight and internal necrosis, in association with *X. compactus* infestations on bay laurel in Italy.

However, the ecological role of this fungus and its interaction with the beetle remain unclear. Further investigations are necessary to: (i) determine whether

X. compactus plays a role in the dissemination of *T. lauri* spores by isolating *T. lauri* from *X. compactus* adults infesting bay laurel and fulfilling Leach's postulates (Hulcr et al. 2020); and (ii) elucidate the potential symbiotic association between *T. lauri* and *X. compactus*.

Acknowledgement

The authors thank Dr. Alberto Fiorenza for his precious help during the laboratory and field procedures.

Abstract

Kockovaella, in the family Cuniculitremaceae of the order *Tremellales*, is a globally distributed genus of blastoconidia-forming fungi. Currently, 23 species have been described and accepted as members of the genus. In this study, five yeast strains were isolated from plant leaf surfaces collected in the Fujian and Guizhou Provinces of China and identified through a combination of morphological and molecular methods. The related phenotypic features and molecular phylogenetic analyses based on ITS, LSU, and RPB1 sequences demonstrated that they were members of three novel *Kockovaella* species: *K. iteae* **sp. nov.**, *K. quanzhouensis* **sp. nov.**, and *K. sambucuse* **sp. nov.** These species were described in detail and discussed relative to other species. This study demonstrated the novel geographical distribution as well as the high species diversity of *Kockovaella* in China and offered more data for further studies in fungal systematics and evolution.

Key words: *Basidiomycota*, phylogenetic analysis, plant leaves, taxonomy, Tremellomycetes

Introduction

Kockovaella (*Tremellales*, Cuniculitremaceae), a ballistoconidiogenous anamorphic yeast genus, was first proposed by Nakase et al. (1991) to accommodate two species, *K. imperatae* and *K. thailandica*. Nine other species were subsequently identified in this genus (Canete-Gibas et al. 1998; Takashima and Nakase 1998; Luong et al. 2000; Fungsin et al. 2002). Prior phylogenetic investigations of the small subunit (SSU) rRNA gene demonstrated that *Kockovaella* was closely related to *Fellomyces* (Nakase et al. 1993). However, the division of *Kockovaella* and *Fellomyces* species into two genera is questionable because further phylogenetic studies indicate a close relationship between the species, and the only difference is the capacity of *Kockovaella* to produce ballistospores (Lopandic et al. 2011; Takashima and Nakase 2011). Nakase et al. (1993) and Nakase (2000) noted that the production of ballistospores may be influenced by cultivation methods and vary from clone to clone. Vegetative reproduction does not reflect the phylogenetic relationships, and a novel approach to the systematics of ballistosporous yeasts should be established (Lopandic et al.

2005a). Liu et al. (2015a) employed seven genes to reconstruct the phylogeny of most described anamorphic and teleomorphic tremellomycetous yeasts. Based on multi-gene phylogenies, eight nonballistoconidium-forming species previously assigned to *Fellomyces* (Lopandic et al. 2011) were transferred to *Kockovaella* (Liu et al. 2015a, b). The latest additions to the genus were *K. libkindii* from the cavity of the bromeliad *Vriesea minarum* in Brazil (Gomes et al. 2016), *K. haikouensis*, *K. ischaemi*, and *K. nitrophila* from the phylloplane in China (Li et al. 2020).

All species of the genus *Kockovaella* are asexual morphs, which are morphologically characterized by the production of blastoconidia on stalk-like conidiophores and budding cells. Some species may produce ballistoconidia and poorly developed pseudohyphae (Lopandic et al. 2011; Takashima and Nakase 2011; Liu et al. 2015b). Physiologically, members of the genus cannot undergo fermentation, possess Q-10 as a predominant ubiquinone, and assimilate diverse carbon sources, but not nitrate (Liu et al. 2015b). Species in this genus can be differentiated via phenotypic characteristics and phylogenetic analyses (Liu et al. 2015b; Li et al. 2020).

To date, 23 species have been accepted as members of the genus *Kockovaella*, with most reported in tropical and subtropical regions, especially in Asia (Lopandic et al. 2011; Takashima and Nakase 2011; Li et al. 2020). Previously, only four species, *K. chinensis*, *K. fuzhouensis*, *K. lichenicola*, and *K. sichuanensis*, were reported in Fujian and Sichuan Provinces of China (Yue 1982; Prillinger et al. 1997). Recently, Li et al. (2020) identified eight *Kockovaella* species in Hainan and Yunnan Provinces, including three new species. Despite these findings, the genus's diversity remains incompletely understood. In this study, five basidiomycetous yeast strains were obtained from Fujian and Guizhou Provinces. Phenotypic characteristics and molecular phylogenetic analyses determined that these strains represent three undescribed species of *Kockovaella*. The aim of the present study was to identify and describe these new taxa using an integrative taxonomic approach.

Materials and methods

Sample collection and yeast isolation

Leaf samples were collected in the Fujian and Guizhou Provinces of China. Yeast strains were isolated from leaf surfaces using the improved ballistospore-fall method outlined by Nakase and Takashima (1993). Fresh leaves were cut into small pieces and affixed with a thin layer of petroleum jelly to the inner lid of a Petri dish containing yeast extract-malt extract (YM) agar (0.3% yeast extract, 0.3% malt extract, 0.5% peptone, 1% glucose, and 2% agar). The mixture was supplemented with 0.01% chloramphenicol to limit bacterial growth. Plates were incubated at 20 °C and monitored daily to assess colony formation. Selected colonies were streaked onto YM agar plates for subsequent purification. Following purification, strains were suspended in YM broth supplemented with 20% (v/v) glycerol and stored at −80 °C for subsequent use. Cultures of the obtained isolates were preserved in the Microbiology Lab at Nanyang Normal University, Henan, China. All collected isolates and their origins are presented in Table 1.

Phenotypic characterization

Morphological, physiological, and biochemical characters were examined according to the standard methods described by Kurtzman et al. (2011). To induce sexual state, single or paired strains were mixed on corn meal agar (CMA; 2% cornmeal infusion and 2% agar), potato dextrose agar (PDA; 20% potato infusion, 2% glucose, and 1.5% agar), and V8 agar (10% V8 juice and 2% agar). The plates were then incubated at 20 °C for up to 8 weeks (Li et al. 2020). Ballistoconidium formation was tested using the inverted-plate method (do Carmo-Sousa and Phaff 1962) after two weeks of incubation on CMA at 17 °C. Glucose fermentation was tested in a liquid medium using Durham fermentation tubes. Carbon and nitrogen assimilation capacities were examined in a liquid medium, with nitrogen tests using a starved inoculum (Kurtzman et al. 2011). Growth at various temperatures (15, 20, 25, 30, 35, and 37 °C) was evaluated through cultivation on YM agar plates. Cell morphology was examined with a LEICA DM2500 camera (LECIA, Wetzlar, Germany) and LASV4.13 software. All new taxonomic descriptions and proposed names were submitted to the MycoBank database (http://www.mycobank.org; 17 June 2024).

DNA extraction, PCR amplification, and sequencing

Genomic DNA was extracted from each strain using the Ezup Column Yeast Genomic DNA Purification Kit, according to the manufacturer's directions (Sangon Biotech Co., Shanghai, China). The ITS region, D1/D2 domain of the LSU rRNA, and a partial segment RPB1 were amplified using the primers ITS1/ITS4 (White et al. 1990), NL1/NL4 (Kurtzman and Robnett 1998), and RPB1-Af and RPB1-Cr (Kurtzman and Robnett 2003), respectively. Amplifications were performed in a 25 µL reaction volume consisting of 9.5 µL of ddH_2O, 12.5 µL of Taq 2X PCR Master Mix with blue dye (Sangon Biotech Co., Shanghai, China), 1 µL of DNA template, and 1 µL of each primer. The ITS region and D1/D2 domain were amplified using an initial denaturation step of 2 min at 95 °C, followed by 35 cycles of 30 s at 95 °C, 30 s at 51 °C, 40 s at 72 °C, and a final extension of 10 min at 72 °C (Toome et al. 2013). Amplification of the partial RPB1 gene was performed using a touchdown PCR protocol as described by

Wang et al. (2014). PCR products were then purified and sequenced by Sangon Biotech Co., Ltd (Shanghai, China) using the same primers. The identity and accuracy of each sequence were determined by comparing them to sequences in GenBank. Assembly was performed with BioEdit v.7.1.3.0 (Hall 1999). All newly generated sequences were deposited in the GenBank database (https://www.ncbi.nlm.nih.gov/genbank/), and the accession numbers are presented in Table 2.

Table 2. Species name, strain numbers, and GenBank accession numbers included in phylogenetic analyses. Entries in bold represent newly generated sequences. The superscript ^{T} indicates type strain.

Phylogenetic analysis

In addition to the newly generated sequences, additional related sequences were also downloaded from GenBank (Table 2) for phylogenetic analyses. The combined ITS, LSU, and RPB1 sequence dataset was used to explore the phylogenetic positions of the newly isolated strains within *Kockovaella*. All *Kockovaella* and *Fellomyces* species listed in Table 2, with available ITS, LSU, and RPB1 sequences, were included as ingroup taxa. *Sterigmatosporidium polymorphum* CBS 8088 was used as the outgroup (Gomes et al. 2016). Because previous phylogenetic studies focusing on *Kockovaella* were mainly based on the ITS and LSU regions, a combined ITS and LSU sequences dataset, comprising all species of *Kockovaella* and *Fellomyces* in Table 2, was used to further differentiate species identities within this genus.

Individual locus sequences were aligned using MAFFT v.7.110 (Katoh and Standley 2013) under the G-INI-I option. Poorly aligned regions were excluded and adjusted manually using MEGA v.11 (Tamura et al. 2021). Aligned sequences of the different loci were concatenated with Phylosuit v.1.2.2 (Zhang et al. 2020). Alignments were improved through manual gap adjustments. Ambiguous areas were excluded from the analysis using Aliview (Larsson 2014).

Phylogenetic analyses were conducted using Maximum Likelihood (ML) and Bayesian Inference (BI) methods. The ML method was performed using RAxML v.8.2.3 (Stamatakis 2014) under a GTRGAMMA model with one thousand rapid bootstrap (BS) replicates. For the BI approach, ModelFinder (Kalyaanamoorthy et al. 2017) was used to infer the appropriate substitution model that would best fit the model of DNA evolution for all combined datasets. The BI method was conducted using MrBayes v.3.2.7a (Ronquist et al. 2012) via the CIPRES Science Gateway. Six simultaneous Markov chains were run for 50 million generations, with trees sampled every 1,000 th generation. The first 25% of trees were discarded as burn-in. The remaining trees were used to calculate the Bayesian posterior probabilities (BPPs) for each clade. The resulting trees were visualized with FigTree v.1.4.3 (Andrew 2016). Branches showing BS values ≥ 50% and BPPs ≥ 0.95 indicated at the nodes.

Results

Molecular phylogeny

The combined dataset of ITS, LSU, and RPB1 resulted in an alignment of 1930 characters (ITS: 1–496, LSU: 497–1118, RPB1: 1119–1930). Among them, there were 1120 constant, 155 variable but parsimony non-informative, and 655 parsimony informative characters. ModelFinder recommended the GTR+I+G evolution model for Bayesian inference. Both ML and BI methods produced similar topologies in the main lineages. The ML-derived topology, along with BS values and BPPs above 50% and 0.95, respectively, is presented (Fig. 1). The phylogeny confirmed *Kockovaella* as a distinct genus (BS/92%; BPP/1). The five newly isolated strains formed three distinct and well-supported groups, separate from other *Kockovaella* species.

The combined dataset of ITS and LSU sequences produced a concatenated alignment of 1,118 characters, including 817 constant, 88 variable but parsimony non-informative, and 213 parsimony informative characters. The GTR+I+G

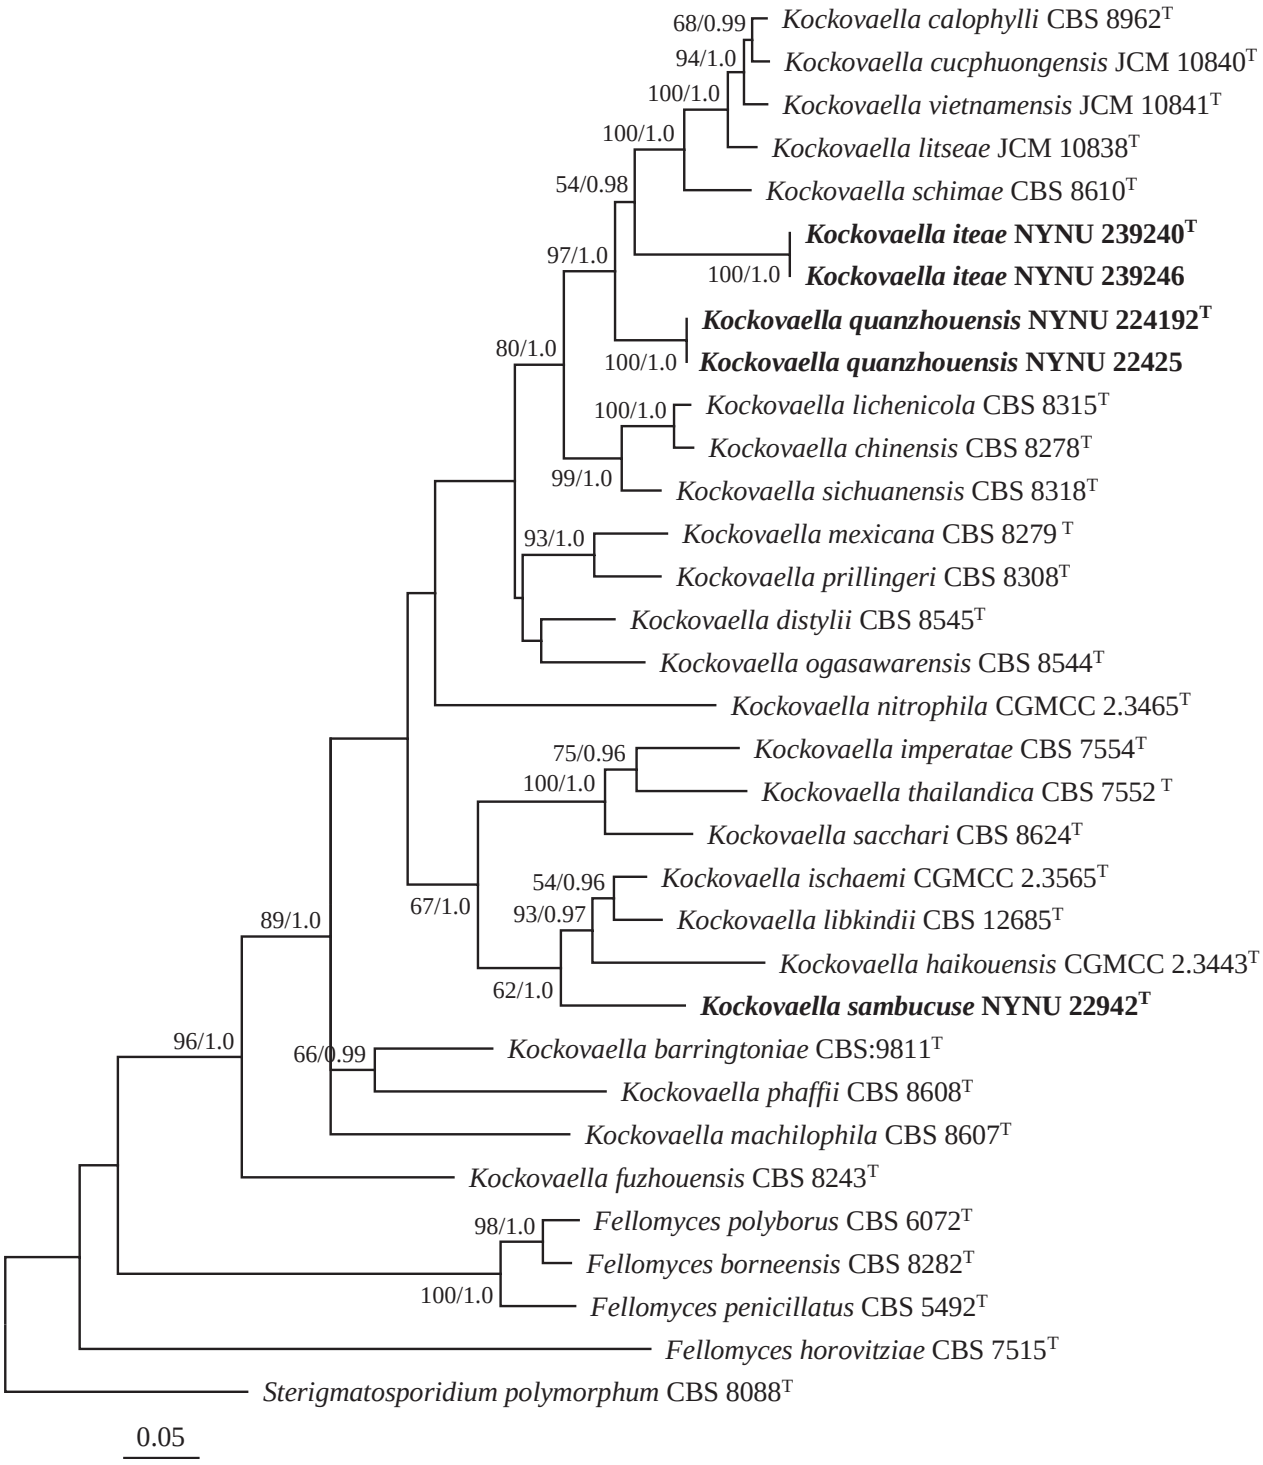

Figure 1. Maximum likelihood phylogenetic tree of *Kockovaella* generated from combined ITS, LSU, and RPB1 sequence data. The tree is rooted with *Sterigmatosporidium polymorphum* CBS 8088. Bootstrap values (BS ≥ 50% and BPPs ≥ 0.95) are displayed near branches. Type strain sequences are marked with (T). New species are highlighted in bold.

evolution model was also adopted for this dataset in Bayesian inference. The ML and BI methods yielded similar topologies in the main lineages. The ML-derived topology, with BS values and BPPs above 50% and 0.95, respectively, is shown (Fig. 2). This tree revealed 23 known *Kockovaella* species, while the newly isolated strains formed three independent groups, consistent with the combined ITS, LSU, and RPB1 dataset phylogeny.

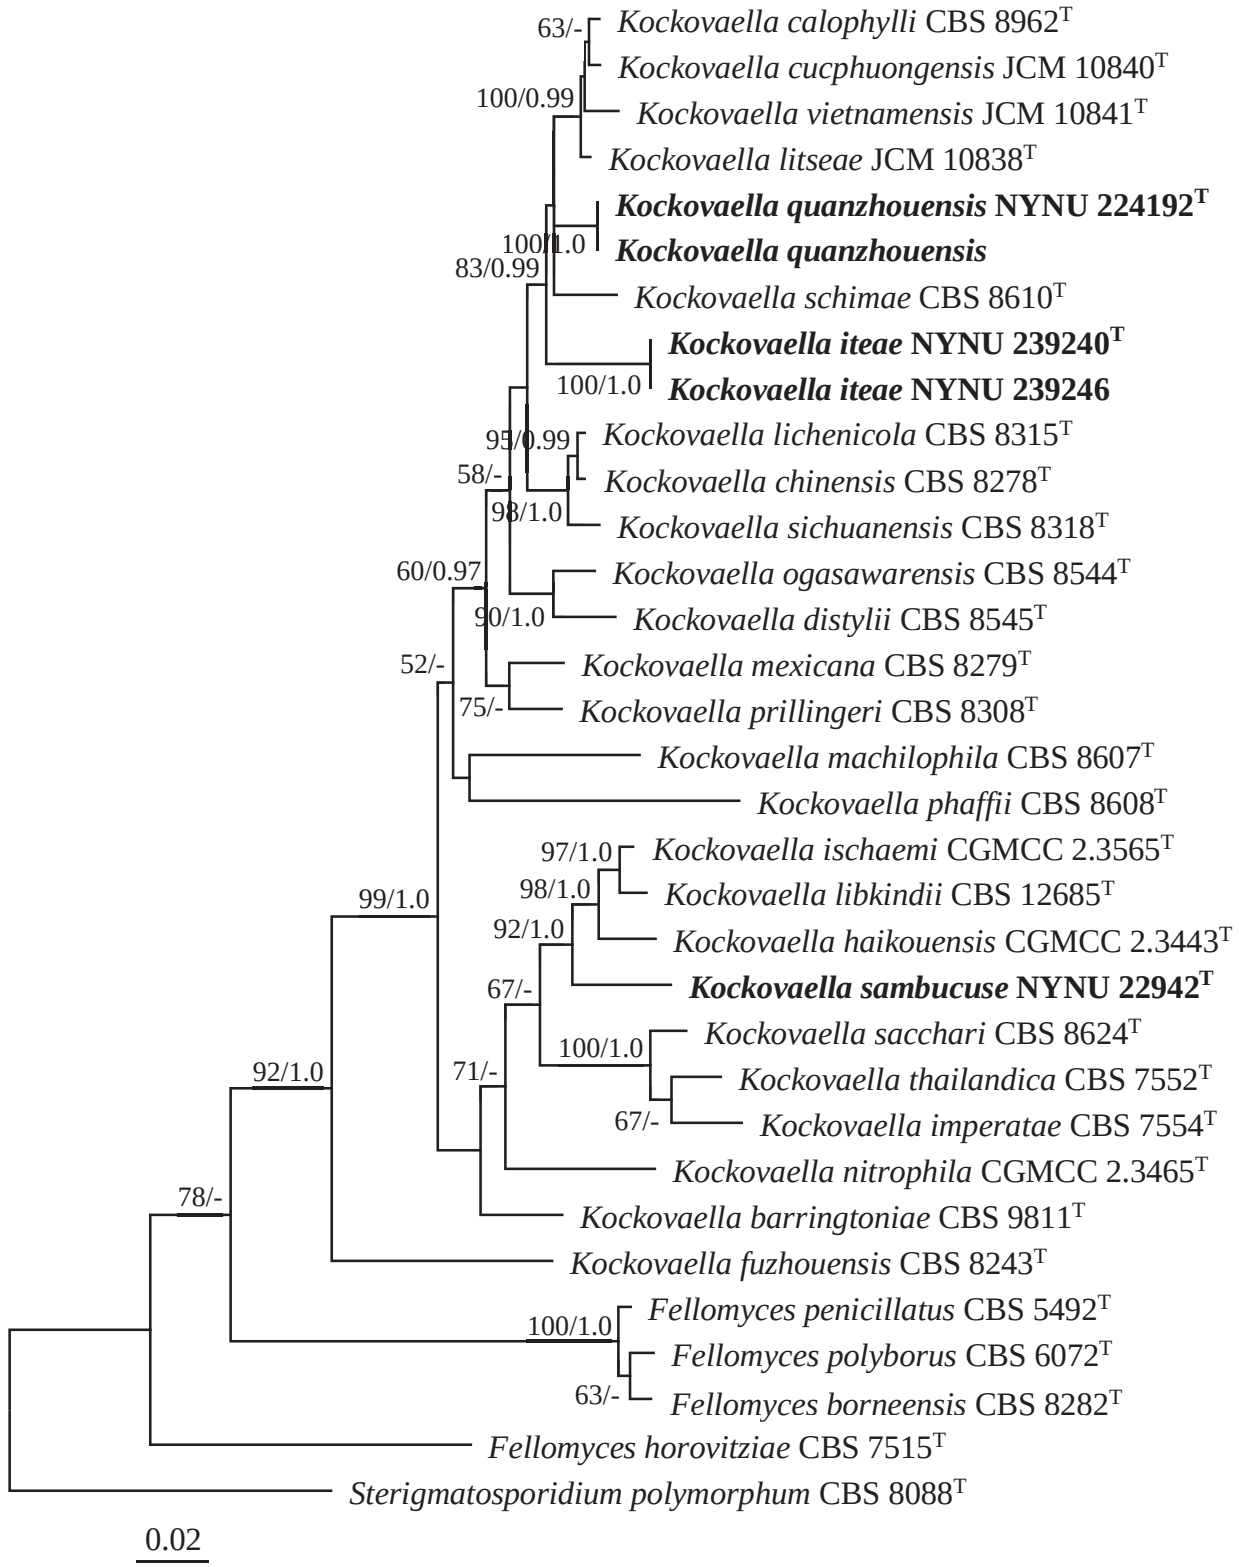

Figure 2. Maximum likelihood phylogenetic tree of *Kockovaella* generated from combined ITS and LSU sequence data. The tree is rooted with *Sterigmatosporidium polymorphum* CBS 8088. Bootstrap values (BS ≥ 50% and BPPs ≥ 0.95) are displayed near branches. Type strain sequences are marked with (T). New species are highlighted in bold.

Groups NYNU 224192 and NYNU 239240, each containing two strains, clustered with *K. calophylli*, *K. cucphuongensis*, *K. litseae*, *K. schimae*, and *K. vietnamensis* in all combined dataset trees (Figs 1, 2). Strains in the NYNU 224192

group had identical ITS and D1/D2 sequences, indicating that they are conspecific. Strains in the NYNU 239240 group, also with identical ITS and D1/D2 sequences, differed from the NYNU 224192 group by 8 nucleotide (nt) (~1.3%) substitutions and 29 nt (~5.8%) mismatches in the D1/D2 and ITS regions, respectively. These two groups differed from their five closest known species by 4–9 nucleotide (nt) (~0.7–1.5%) substitutions and 14–13 nt (~2.8–4.4%) mismatches in the D1/D2 and ITS regions, respectively. Strain NYNU 22942 clustered with *K. haikouensis*, *K. ischaemi*, and *K. libkindii* with 62% BS and 1.0 BPPs support in the combined ITS, LSU, and RPB1 phylogenetic tree (Fig. 1). It formed a well-supported clade with these species in the combined ITS and LSU dataset tree (92% BS, 1.0 BPPs; Fig. 2), differing from its nearest relatives by 9–10 nucleotide (nt) (~1.5–1.7%) substitutions and 25–27 nt (~4.7–5.1%) mismatches in the D1/D2 and ITS regions, respectively.

The above sequence comparisons suggested that the five novel strains represent three novel species within the genus *Kockovaella*.

Taxonomy

***Kockovaella iteae* C.Y. Chai & F.L. Hui, sp. nov.**
MycoBank No: 854381
Fig. 3

Etymology. The specific epithet *iteae* refers to *Itea*, the plant genus from which the type strain was isolated.

Type. China • Guizhou Prov.: Guiyang City, East Mountain Park, in the phylloplane of *Itea yunnanensis*, 15 Sept 2023, D. Lu, NYNU 239240 (holotype GDMCC 2.503^T preserved as a metabolically inactive state, culture ex-type PYCC 9996).

Description. On YM agar after 7 days at 20 °C, the streak culture is white to cream-colored, butyrous, smooth and glistening, with an entire margin. After 7 days in YM broth at 20 °C, cells are ellipsoidal or ovoid, 1.5–3.6 × 3.6–5.5 µm, single or pairs, and reproduced by polar budding and the formation of stalked conidia. The conidia are separated at the distal end of the stalks from parent cells. After 1 month at 20 °C, a ring and sediment are present. In Dalmau plate culture on CMA, pseudohyphae are not formed. Sexual structures are not observed on PDA, CMA or V8 agar. Ballistoconidia are symmetrical and apiculate, 1.8–2.4 × 2.7–3.3 µm. Glucose fermentation is absent. Glucose, inulin (delayed and weak), sucrose, raffinose, melibiose, galactose, lactose, trehalose, maltose, melezitose, cellobiose, salicin (delayed and weak), L-rhamnose, D-xylose, L-arabinose, D-arabinose (delayed), 5-keto-D-gluconate (delayed and weak), D-ribose (delayed), erythritol (delayed), ribitol, galactitol, D-mannitol, D-glucitol, myo-inositol, succinate, citrate, D-glucosamine, N-acetyl-D-glucosamine, 2-keto-D-gluconate (delayed), D-glucuronate, and glucono-1.5-lactone are assimilated as sole carbon sources. Methyl-α-D-glucoside, L-sorbose, methanol, ethanol, glycerol, DL-lactate, and D-gluconate are not assimilated. Ethylamine (delayed) and L-lysine are assimilated as sole nitrogen sources. Nitrate, nitrite, and cadaverine are not assimilated. Maximum growth temperature is 25 °C. Growth in vitamin-free medium is positive. Growth on 50% (w/w) glucose-yeast extract agar is negative. Starch-like substances are not produced. Urease activity is positive. Diazonium Blue B reaction is positive.

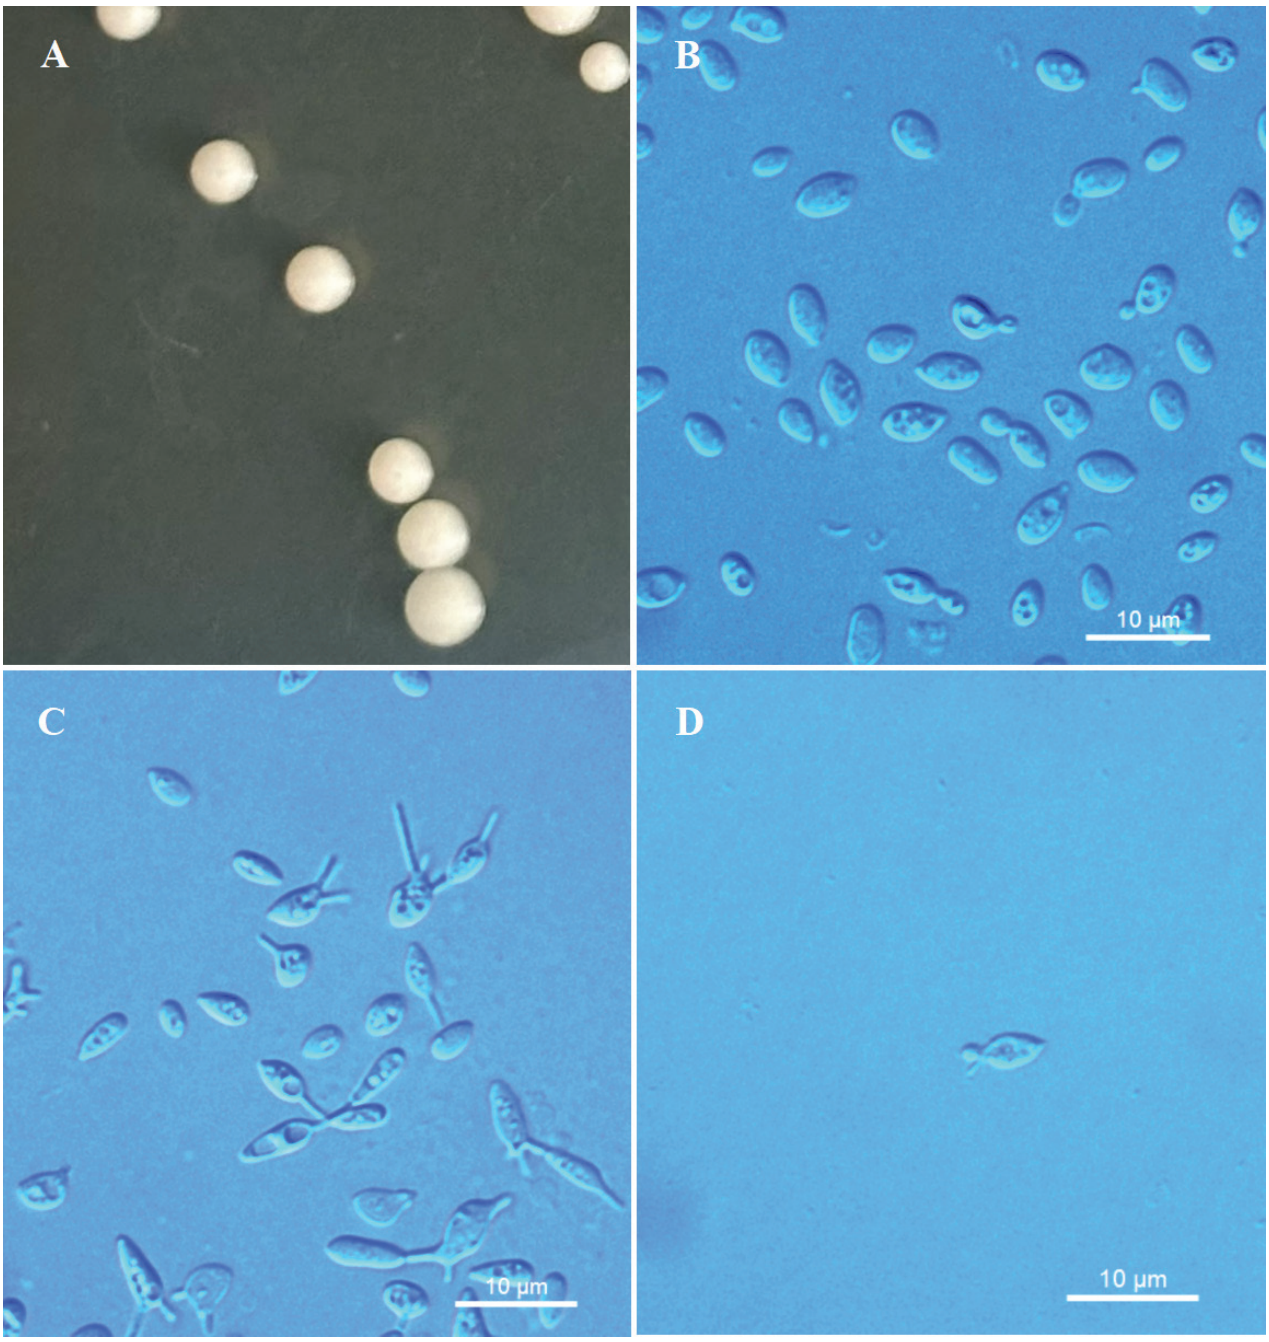

Figure 3. Morphological characteristics of *Kockovaella iteae* sp. nov. GenBank accession numbers. holotype GDMCC 2.313^{T} (ITS: OP566879, D1/D2: OP566878).

Note. Physiologically, *Kockovaella sambucuse* sp. nov. differs from three closely related species, *K. haikouensis*, *K. ischaemi*, and *K. libkindii*, in its ability to assimilate L-sorbose and its inability to assimilate cadaverine (Table 3).

Discussion

Phylogenetic analyses grouped 26 species of *Kockovaella* together (Figs 1, 2), including three new species from China: *K. iteae* sp. nov., *K. quanzhouensis* sp. nov., and *K. sambucuse* sp. nov. Our results are consistent with previous observations (Gomes et al. 2016; Li et al. 2020), and provide additional insights into the phylogeny and taxonomy of *Kockovaella*.

Kockovaella sambucuse sp. nov. described in this study was represented by only one strain from our isolations. Despite a number of samples collected in different locations for two consecutive years, we were unable to confirm the occurrence of this yeast to obtain additional strains. The description of single-strain species will add to an understanding of yeast phylogeny and species diversity, which would be unknown if new species descriptions were limited to those taxa for which multiple strains were available (Kurtzman 2010).

Fellomyces horovitziae was first reported in Germany by Spaaij et al. (1991) based on phenotypic characteristics. However, our phylogenetic analysis did not support its placement in *Fellomyces*, despite its morphological similarity to other species in the genus, as it forms conidia on stalks (Lopandic et al. 2011). This result is similar to the results of previous phylogenetic analyses based on the single LSU sequence and the combined ITS and LSU sequences (Gomes et al. 2016; Li et al. 2020). Therefore, further analyses using more molecular or genomic data are needed to clarify its phylogenetic position.

Kockovaella species are widely distributed across various habitats. They are commonly identified as epiphytic fungi on flowers (Yue 1982), leaves (Canete-Gibas et al. 1998; Hamamoto et al. 1998; Takashima and Nakase 1998; Luong et al. 2000; Fungsin et al. 2002; Lopandic et al. 2011; Li et al. 2020), and lichens (Prillinger et al. 1997; Lopandic et al. 2005b) in temperate and subtropical climate regions. *K. libkindii*, for example, has been found in water cavities (Gomes et al. 2016), where it forms a minor component of the yeast community, likely vectored by insects visiting these microhabitats (Gomes et al. 2016). In this study, three new *Kockovaella* species were associated with plant leaves, similar to other species in the genus. Other species identified from these samples include *Bullera alba*, *Derxomyces boekhoutii*, *Erythrobasidium primogenitum*, *Moesziomyces antarcticus*, *Moesziomyces aphidis*, *Symmetrospora coprosmae*, and *Tilletiopsis washingtonensis*, all common representatives in the phyllosphere (Nakase 2000; Kruse et al. 2017). The discovery of these three

new species highlights the widespread natural distribution of *Kockovaella* species on plants, emphasizing the need for extensive sampling and detailed molecular and phenotypic analyses to fully understand their global diversity.

Conclusions

In the present study, five phyllosphere-inhabiting yeast strains were identified as three new *Kockovaella* species, *K. iteae* sp. nov., *K. quanzhouensis* sp. nov., and *K. sambucuse* sp. nov., based on morphological and molecular phylogenetic analyses, which provides us with further understanding of this genus diversity in China. In the future, we firmly believe that more and more species of the genus will be isolated from more plants around the world.

Acknowledgments

The authors are very grateful to their colleagues at the School of Life Science, Nanyang Normal University, including Dan Lu for providing specimens; Ting Lei for help with phylogenetic analysis; Shan Liu and Ya-Zhuo Qiao for help with morphological observations.

Abstract

Absidia is distributed worldwide and primarily isolated from soil, feces, and decaying plants. The genus was initially classified into Absidiaceae and then Mucoraceae, and currently belongs to Cunninghamellaceae and is further divided into *Absidia* s.s., *Lichtheimia*, and *Lentamyces*. Three new species of *Absidia* s.s. are identified and described from soil in Hainan Province of China based on morphological characteristics, molecular data, and maximum growth temperatures as well. They are named based on distinct shapes of projections on columellae: *A. crystalloides* **sp. nov.** (crystal-like), *A. pacifica* **sp. nov.** (pacifier-like), *A. pateriformis* **sp. nov.** (bowling-like). In SSU-ITS-LSU-TEF-*Act* phylogram, the *A. crystalloides* is closely related to *A. oblongispora* and *A. heterospora*, the *A. pacifica* is a sister group with *A. edaphica*, and the *A. pateriformis* has a close relationship with *A. jiangxiensis*. This study enriches the species diversity of *Absidia* in China.

Key words: Basal fungi, fungal diversity, molecular phylogeny, Mucorales taxonomy

Introduction

The genus *Absidia* Tiegh. 1878 belongs to Mucoromycota, Mucoromycetes, *Mucorales*, Cunninghamellaceae (http://www.indexfungorum.org/, accessed on 15 March 2024). The type species of this genus is *A. reflexa* Tiegh. 1878 (van Tieghem 1876). Its classification has been a subject of controversy for over a century. *Absidia* was initially classified in the family Absidiaceae (von Arx 1982) and later in the family Mucoraceae (Benny et al. 2001). Eventually, it was included in the family Cunninghamellaceae (Ashton 2009). Recently, *Absidia* s.l. was divided into *Absidia* s.s., *Lichtheimia* Vuill, and *Lentamyces* Kerst. Hoffm. & K. Voigt based on growth temperature, molecular phylogeny, and morphological characteristics (Hoffmann et al. 2007; Hoffmann and Voigt 2009; Hoffmann 2010). The *Absidia* is distributed globally, with reports

of its presence in Estonia (1621), Australia (839), Czechia (688), Argentina (514), and Lithuania (422) (https://www.gbif.org/, accessed on 15 March 2024). The genus is primarily found in soil, but it can also be detected in feces, air, decaying plants, and waste materials (Zhang et al. 2018; Lima et al. 2020; Zong et al. 2021; Hurdeal et al. 2021, 2023). Currently, there are 131 records of *Absidia* species, varieties and subspecies (http://www.indexfungorum.org/, accessed on 15 March 2024). Zhao et al. (2023) discovered 15 novel *Absidia* species from Beijing, Yunnan, Qinghai, and Xinjiang of China, along with three Chinese new record species. This significant contribution has substantially augmented the Chinese database on *Absidia* species resources and enhanced the taxonomic framework of Mucoromycota (Zhao et al. 2023). *Absidia* is frequently employed in the biotransformation of various types of natural products, including hydroxylation, glycosylation, reduction reactions, and more. Both *A. caerulea* and *A. glauca* can be utilized for the biotransformation of flavones and flavanones (Sordon et al. 2019). *A. spinosa* is applied in the biotransformation of cresol red (Kristanti et al. 2016). Additionally, it should be noted that species in those genera closely related to *Absidia* plays a vital role as a pathogen causing human mucormycosis (Constantinides et al. 2008); specifically, *A. corymbifera* (=*Lichtheimia corymbifera*) is associated with meningitis (Mackenzie et al. 1988) and keratitis (Varona et al. 2015). The typical characteristics of *Absidia* include stolons, rhizoids, sporangia, sporangiophores, etc. The sporangiophores can be branched or unbranched and may grow erect or curved. If a collar is present, it is easily noticeable. One or two protrusions are present on columellae. It produces zygospores that are typically spherical in shape (van Tieghem 1876; Hoffmann et al. 2007; Zong et al. 2021; Zhao et al. 2023).

While investigating soil microbial resources in Hainan Province, three novel *Absidia* species (*A. crystalloides* sp. nov., *A. pacifica* sp. nov., and *A. pateriformis* sp. nov.) were discovered. These new species are illustrated in this article based on morphological features, molecular phylogeny, and maximum growth temperatures.

Materials and methods

Sample collection and strain isolation

The strains were isolated from soil samples collected from Jianfengling Mountains and Bawangling Mountains in Hainan Province in October 2023. Samples were subjected to the moist-chamber culture and plate dilution coating methods (Zhao et al. 2022a, 2022b). The moist-chamber culture involved evenly sprinkling 1 g of soil onto the surface of PDA plates (potato 200 g, dextrose 20 g, agar 20 g, distilled water 1000 mL), sealing with a parafilm, inverting the plates, and incubating at 25 °C in darkness. After three days, microscopic observation was conducted, and the target strain was purified using an inoculating loop upon the formation of sporangia of *Absidia*. The plate dilution coating included taking 1 g of soil, diluting with 1 mL of sterile water through swirling and shaking until reaching dilutions of 10^{-2}, 10^{-3}, and 10^{-4}. Subsequently, 200 µL of the diluted solutions (10^{-3} and 10^{-4}) were evenly applied onto the surface of PDA plates using sterile triangle spreaders. The plates were sealed with a

parafilm and inverted for cultivation at 25 °C in darkness. After three days, purification of target strains was performed. The target strain was stored in four freezing tubes and preserved in a refrigerator at a temperature of 4 °C. The purified strains were preserved in the China General Microbiological Culture Collection Center, Beijing, China (CGMCC). Additionally, they were stored in the Shandong Agricultural University Culture Collection (SAUCC) and Shandong Normal University, Jinan, China (XG). The dried cultures were maintained in the Herbarium Mycologicum Academiae Sinicae, Beijing, China (HMAS).

Morphology and maximum growth temperature

The PDA cultured colonies were incubated at a temperature of 25 °C, and on the seventh day of colony growth, photographs were captured from both the front and back using a digital camera (Canon Powershot G7X). The colonies were allowed to grow for a period of five to six days, and then their microscopic morphology was observed using Olympus SZX10 stereomicroscope and Olympus BX53 microscope. Morphological features were assessed by measuring 20 variables, including minimum and maximum values. Two strains were inoculated on PDA containing 0.1% lecithin for pairing experiments, and the petri dishes were sealed with parafilm to maintain moisture. To determine the maximum growth temperature, a gradient method (Zheng et al. 2007, 2009; Zheng and Liu 2009; Zong et al. 2021; Zhao et al. 2022b) was employed whereby the colonies were initially cultured at 25 °C for two days followed by an increase in temperature by 1 °C each day until no further growth was observed. This determined the maximum temperature. The species were classified and described, and the taxonomic information was uploaded to Fungal Name repository (https://nmdc.cn/fungalnames/).

DNA extraction, PCR amplification, and sequencing

In this study, the CTAB method (Doyle and Doyle 1990; Guo et al. 2000) was employed for DNA extraction. Subsequently, the extracted DNA underwent polymerase chain reaction (PCR) targeting five segments, namely SSU (small subunit), ITS (internal transcribed spacer), LSU (large subunit of ribosomal DNA), TEF-1α (translation elongation factor 1 alpha), and *Act* (actin). For PCR amplification, five primer pairs were utilized: NS1/NS4, ITS4/ITS5, LR0R/LR5, EF1-983F/TEF1LLErev, and Act-1/Act-4R (Table 1). The amplification reaction solution (25 μL) contained 12.5 μL 2× Hieff Canace Plus PCR Master Mix with dye (Yeasen Biotechnology, Shanghai, China, Cat No. 10154ES03), 9.5 μL ddH_2O, 1 μL forward primer (10 μM), 1 μL reverse primer (10 μM) and 1 μL DNA template (1 ng/μL). The PCR programs are listed in Table 1. Following PCR amplification, the products were subjected to electrophoresis using 2% agarose gels and observed under UV light to confirm successful amplification (Zhang et al. 2021). Amplified products were purified through recovery using a Gel Extraction Kit (Cat# AE0101-C, Shandong Sparkjade Biotechnology Co., Ltd.). Tsingke Biotechnology Co., Ltd. (Qingdao, China) was responsible for DNA sequencing and primer synthesis. MEGA v. 7.0 (Kumar et al. 2016) was employed for sequence assembly. Finally, the sequence was compared against NCBI (National Center for Biotechnology Information) database to search relatives.

Phylogenetic analyses

Referring to the newly published article about *Absidia* (Zhao et al. 2023), the sequences were downloaded for phylogenetic analysis from the NCBI (https://www.ncbi.nlm.nih.gov/), and the GenBank accession numbers of the sequences used are shown in Table 2. All sequences were compared and manually corrected using MEGA v.7.0 (Kumar et al. 2016). The phylogeny of *Absidia* was inferred using the maximum likelihood (ML), Bayesian inference (BI), and maximum parsimony (MP) algorithms. ML analysis was conducted using RaxML 8.2.4 in CIPRES Science Gateway V. 3.3 (https://www.phylo.org/), with 1,000 bootstrap replicates (Miller et al. 2010; Stamatakis 2014). Eight cold Markov chains ran simultaneously for two million generations using the GTR + I + G model for BI analysis, and sampling once every 1,000 generations (Huelsenbeck and Ronquist 2001; Nylander 2004). MP analysis was performed for 1,000 bootstrap replicates by the heuristic search option with reconnection and bisection (Swofford 2002). The result of phylogenetic analysis was checked and adjusted using FigTree v.1.4.4 (http://tree.bio.ed.ac.uk/software/figtree), followed by beautifying the phylogenetic tree with Adobe Illustrator CC 2019. Base differences among the three new species and related species were calculated with MEGA7, with evolutionary distances and standard deviations being shown below and above the diagonal line, respectively. (Kumar et al. 2016).

Result

Phylogeny

Phylogenetic analyses of SSU, ITS, LSU rDNA, TEF-1α and *Act* were conducted for a total of 91 sequences, composing 36 species of *Absidia* and two outgroups, *Cunninghamella blakesleeana* (CBS 782.68) and *C. elegans* (CBS 167.53). The phylogenetic analysis encompassed a total of 4,785 characters, with 516 of SSU, 996 of ITS, 1,874 of LSU, 743 of TEF-1α, 660 of *Act* characters (Suppl. material 2). Among these, there were 2,712 constant and 515 variable but parsimony-uninformative characters, while the remaining 1558 characters were parsimony-informative. Both the maximum likelihood (ML) and Bayesian Inference (MB) method yielded highly similar trees with almost identical topologies. The phylogenetic relationship was represented using the topological structure obtained from ML analyses, with a final optimization likelihood of -53757.555363 (Fig. 1). The six strains of *Absidia* isolated in this study were divided into three individual branches representing *A. pacifica*, *A. crystalloides*, and *A. pateriformis*. In order to further resolve the three

Notes: The newly discovered species identified in the study are in bold. Ex-type strains are marked with a "*". NA stands for "not available".

new species and their related species, genetic distances of each DNA marker were calculated and shown in the Suppl. material 1: PDF. The *A. pacifica* is closely related to *A. edaphica* (MLBV = 100, BIPP = 1.00), with genetic distances of 0.739 (ITS), 0.699 (LSU), 0.008 (*Act*), and 0.003 (SSU). The *A. crystalloides* is closely related to *A. oblongispora* and *A. heterospora* (MLBV = 100, BIPP = 1.00), with genetic distances of 0.760 (ITS), 0.716 (LSU), and 0.008 (*Act*) from *A. oblongispora*, and 0.657 (ITS), 0.721 (LSU), and 0.000 (SSU) from *A. heterospora*. The *A. pateriformis* is closely related to *A. jiangxiensis* (MLBV = 100, BIPP = 1.00), with genetic distances of 0.724 (ITS), 0.763 (LSU), 0.002 (TEF-1α), 0.018 (*Act*), and 0.003 (SSU).

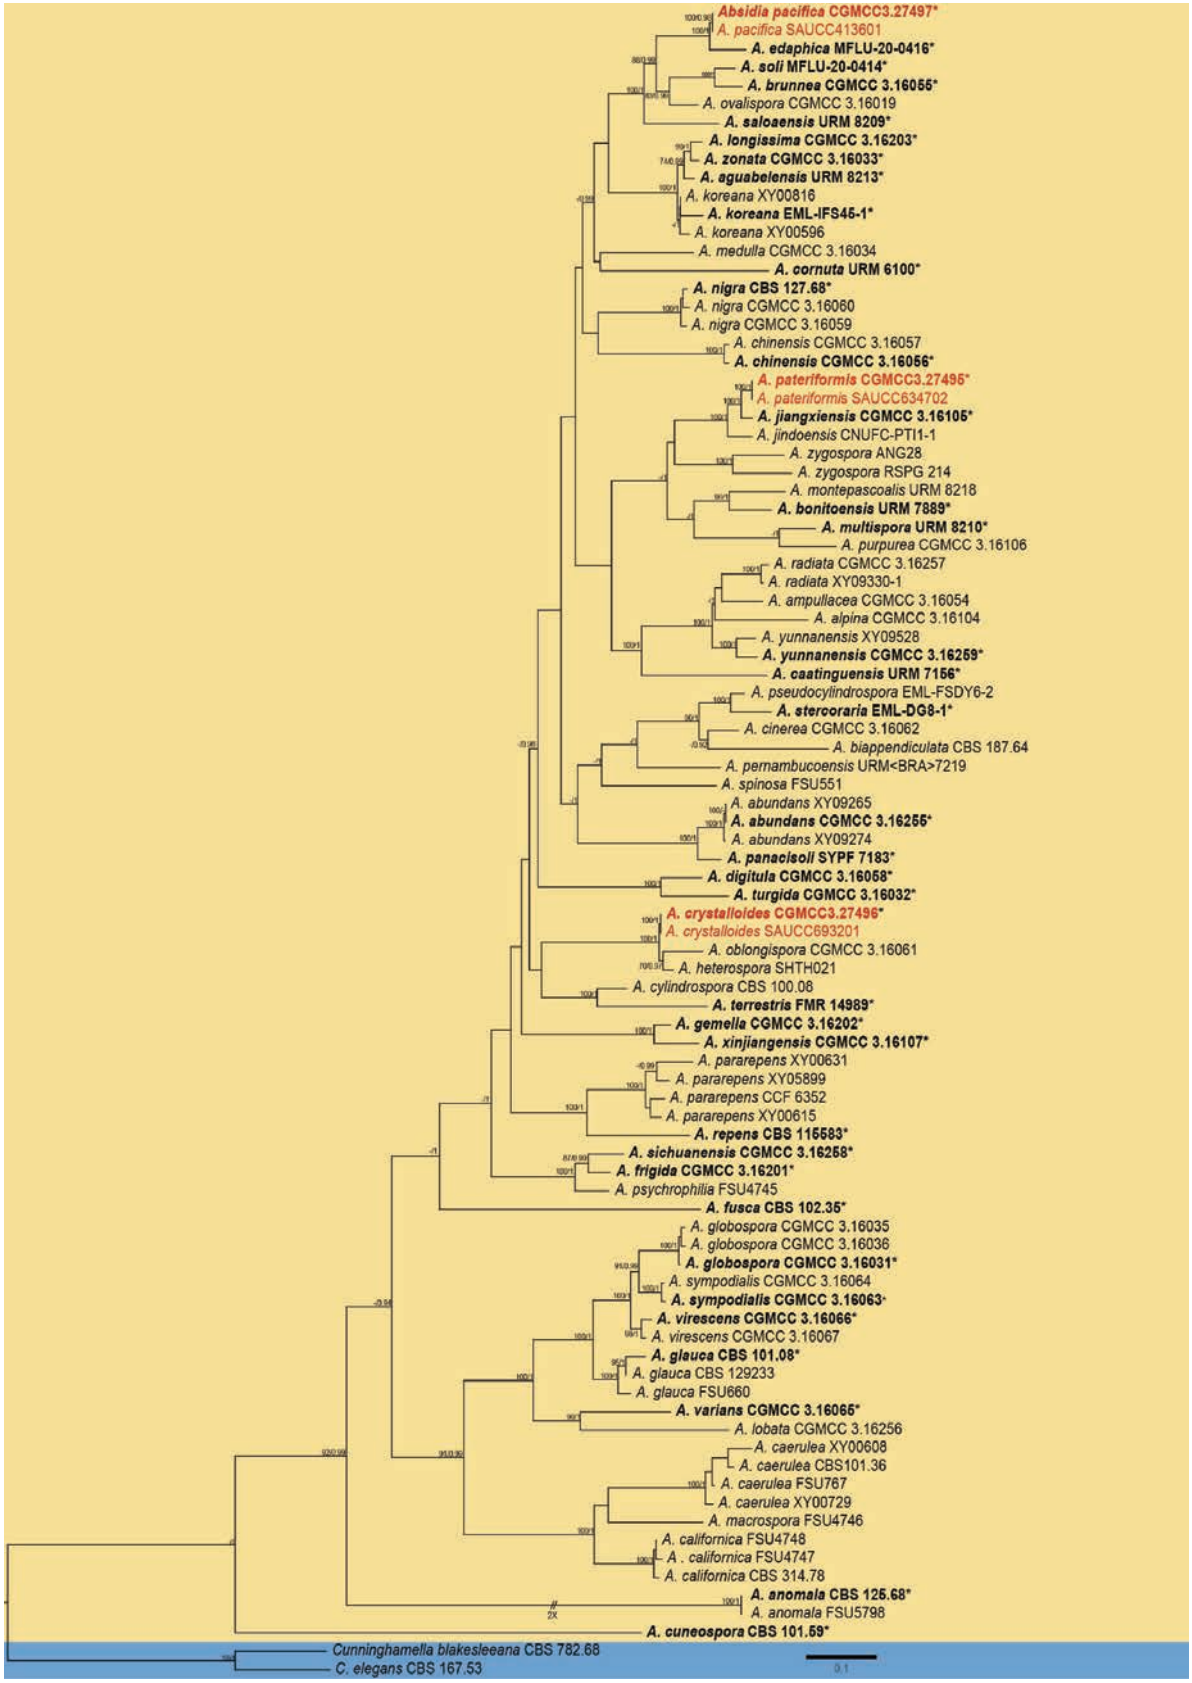

Figure 1. The maximum likelihood phylogram of *Absidia* based on SSU, ITS, LSU rDNA, TEF-1α and *Act* sequences with *Cunninghamella blakesleeana and C. elegans* as outgroups. The branches are marked with the Maximum Likelihood Bootstrap Value (left, MLBV ≥ 70%) and Bayesian Inference Posterior Probability (right, BIPP ≥ 0.90) at nodes. The six newly identified strains are denoted in red. Ex-type or ex-epitype strains are indicated with "*".

Taxonomy

The present study reported three novel species, namely *Absidia pacifica* sp. nov., *A. crystalloides* sp. nov., and *A. pateriformis* sp. nov., from soil samples collected in Hainan, China. They are described and illustrated as follows.

***Absidia pacifica* M.F. Tao, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571915
Fig. 2

Type. China • Hainan Province, Changjiang County, Bawangling National Forest Park (19.08593°N, 109.12275°E), from soil, 14 Oct 2023, M.F. Tao and X.Y. Liu, holotype HMAS 352924, ex-holotype living culture CGMCC3.27497, living cultures XG06955-16 or SAUCC6955-16.

Etymology. The epithet *pacifica* (Lat.) refers to the pacifier-shaped projections.

Description. Mycelia hyaline at first, becoming brownish when mature, aseptate or irregularly septate with age, branched. Stolons hyaline to brownish, smooth, branched, 4.2–8.8 µm in diameter. Rhizoids well-developed, root-like, hyaline, simply branched. Stolons present. Sporangiophores growing from stolons, erect or slightly bent, unbranched, hyaline, single or 2–6 in whorls, 79.1–128.7 µm long, 3.0–6.5 µm wide, sometimes with a swelling beneath sporangia, with a septum 11.3–29.6 µm below apophyses. Apophyses obvious, small, hyaline, slightly pigmented, 4.6–8.4 µm wide at the base and 9.8–20.0 µm wide at the top. Sporangia globose, smooth, dark brown, deliquescent-walled, 23.6–39.2 µm long, 19.0–33.7 µm wide. Collars absent or present. Columellae mostly globose, occasionally oval, 12.8–22.1 µm long, 9.5–21.8 µm wide. Projections pacifier-like, 4.1–7.5 µm long, 1.8–3.9 µm wide. Sporangiospores variously shaped, mostly cylindrical or subglobose, smooth, hyaline, 2.8–6.2 µm long, 2.0–3.9 µm wide. Chlamydospores absent. Zygospores not found.

Culture characteristics. Colonies on PDA at 25 °C for 7 days, reaching 85 mm in diameter, exhibiting an average growth rate of approximately 11.4–12.1 mm/d, white initially, brown with age, irregularly concentrically zonate with ring, flower-shaped, irregularly in reverse, with adjoining satellite colonies at edge.

Maximum growth temperature. 35 °C.

Additional specimen examined. China • Hainan Province, Changjiang County, Seven Forks (19.11750°N, 109.15000°E), from soil, 11 Apr 2023, M.F. Tao and X.Y. Liu, living culture XG04136-4 or SAUCC413601; • China, Hainan Province, Changjiang County, Bawangling National Forest Park (19.08593°N, 109.12275°E), from soil, 14 Oct 2023, M.F. Tao and X.Y. Liu, living culture XG06955-15 or SAUCC6955-15.

Notes. Phylogenetically, *A. pacifica* was closely related to *A. edaphica*. Morphologically, the sporangiophores of *A. pacifica* was longer than that of *A. edaphica* (3.0–6.5 µm vs 2.5–5.4 µm), and the distance between the septum and apophysis was shorter in *A. pacifica* than that in *A. edaphica* (11.3–29.6 µm vs 20–33.5 µm). The columellae of *A. pacifica* were larger than those of *A. edaphica* (9.5–21.8 × 12.8–22.1 µm vs 5–9.5 × 6.5–20 µm). Additionally, some columellae in *A.pacifica* lacked a collar structure. The overall length of spores in *A.pacifica* was slightly larger than that in *A. edaphica* (2.8–6.2 µm

Figure 2. *Absidia pacifica* (holotype: HMAS 352924) **a** obverse and reverse of the culture on PDA **b, d, e** sporangia **c** swellings in hyphae **f, g** columellae **h** rhizoids **i** sporangiospores. Scale bars: 10 μm (**b–i**).

vs 3.5–5.5 μm), and the shape of sporangiospores in *A. pacifica* was more diverse. Physiologically, the maximum growth temperature for *A. pacifica* was lower than that of *A. edaphica* (35 °C vs 36 °C) (Hurdeal et al. 2021).

Absidia crystalloides **M.F. Tao, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571916
Fig. 3

Type. China • Hainan Province, Changjiang County, Bawangling National Forest Park (19.08593°N, 109.12275°E), from soil, 14 Oct 2023, M.F. Tao and X.Y. Liu, holotype HMAS 352925, ex-holotype living culture CGMCC3.27496, living cultures XG06948-15 or SAUCC6948-15.

Etymology. The epithet *crystalloides* (Lat.) refers to the crystal-like projections.

Description. Mycelia white at first and gradually turning to dark brown, branched, subhyaline to hyaline, aseptate or irregularly septate with age. Rhizoids well-developed, root-like, branched. Stolons hyaline, branched, brownish, smooth, 3.1–7.8 μm in diameter. Sporangiophores growing on stolons, mostly unbranched or simply branched, erect or slightly bent, smooth, single or 2–4 in whorls, 55.8–109.3 μm long, 2.6–4.7 μm wide, with one septum 12.8–24.1 μm below sporan-

gia. Sporangia mainly globose, rarely pyriform, dark brown, smooth, subhyaline, deliquescent-walled, 23.0–28.0 µm long, 23.4–28.0 µm wide. Apophyses distinct, light brown, subhyaline, 3.9–9.4 µm wide at the base and 7.4–17.8 µm wide at the top. Collars clearly present, hyaline. Columellae subglobose to globose, smooth, 9.7–12.6 µm long, 11.7–19.5 µm wide. Projections present or absent, if present, single, crystal-like, 3.1–3.5 µm long, 1.8–2.2 µm wide. Sporangiospores smooth, hyaline, oval or fabiform, exhibiting a slight constriction at the center, 3.1–4.1 µm long, 2.1–2.8 µm wide. Chlamydospores absent. Zygospores not found.

Culture characteristics. Colonies on PDA at 25 °C for 7 days, reaching 65 mm in diameter, exhibiting an average growth rate of approximately 8.6–9.3 mm/d, white initially, gradually becoming dark brown when mature, irregularly concentrically zonate with ring, irregularly in reverse.

Maximum growth temperature. 32 °C.

Additional specimen examined. China • Hainan Province, Changjiang County, Bawangling National Forest Park (19.08593°N, 109.12275°E), from soil, 14 Oct 2023, M.F. Tao and X.Y. Liu, living culture XG06932-1 or SAUCC693201, XG06948-17 or SAUCC6948-17.

Notes. Phylogenetically, *A. crystalloides* was closely related to *A. oblongispora* and *A. heterospora*. Compared with *A. oblongispora*, the *A. crystalloides* exhibited a smaller stolon diameter (3.1–7.8 µm vs 4.0–9.5 µm), the septum was po-

Figure 3. *Absidia crystalloides* (holotype: HMAS 352925) **a** obverse and reverse of the culture on PDA **b** rhizoids **c, d** columellae **e, f** sporangia **g** sporangiospores. Scale bars: 10 µm (**b–g**).

sitioned at a greater distance from apophyses (12.8–24.1 µm vs 9.5–16.0 µm), while sporangiophores were located at a shorter distance (55.8–109.3 µm vs 33.0–300.0 µm), apophyses had a wider base width (3.9–9.4 µm vs 3.5–7.5 µm). Physiologically, the maximum growth temperature of *A. crystalloides* was higher (32 °C vs 31 °C). In comparison to *A. heterospora*, the *A. crystalloides* possessed two forms of sporangiospores and had a smaller columella diameter (11.7–19.5 µm vs 10.5–34 µm) (Hesseltine and Ellis 1964; Zhao et al. 2023).

Absidia pateriformis **M.F. Tao, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571917
Fig. 4

Type. China • Hainan Province, Ledong County, Jianfengling National Forest Park (18.74540°N, 108.96716°E), from soil, 13 Oct 2023, M.F. Tao and X.Y. Liu, holotype HMAS 352926, ex-holotype living culture CGMCC3.27495, living cultures XG06347-1 or SAUCC6347D-1.

Etymology. The *pateriformis* (Lat.) refers to its bowling-like projections.

Description. Mycelia white at first and gradually turning to light brown, aseptate or septate, branched. Rhizoids well-developed, root-like, simply branched.

Figure 4. *Absidia pateriformis* (holotype: HMAS 352926) **a** obverse and reverse of the culture on PDA **b** sporangiospores **c** rhizoids **d** columellae **e–g** sporangia. Scale bars: 10 µm (**b–g**).

Stolons hyaline, branched, smooth, 4.4–9.2 μm in diameter. Sporangiophores growing on stolons, erect or slightly bent, mostly unbranched or simply branched, smooth, single or 2–4 in whorls, 33.4–156.5 μm long, 2.7–6.8 μm wide. Sporangia globose to pyriform, smooth, hyaline, deliquescent-walled, 16.8–30.6 μm long, 11.2–26.7 μm wide, and with a septum 9.4–20.6 μm below sporangia. Apophyses obvious, gradually widening from the base to the top, 3.8–11.4 μm wide at the base and 7.1–24.3 μm wide at the top, light brown, hyaline. Collars absent or present. Columellae mostly globose, occasionally oval, 10.9–25.1 μm long, 8.2–21.0 μm wide. Projections obvious, bowling-like, hyaline, single, 3.3–6.7 μm long, 1.2–4.0 μm wide. Sporangiospores smooth, hyaline, oval or globose, 3.1–4.2 μm long, 2.7–4.0 μm wide. Chlamydospores absent. Zygospores not found.

Culture characteristics. Colonies on PDA at 25 °C for 7 days, reaching 80 mm in diameter, exhibiting an average growth rate of approximately 10.7–11.4 mm/day, initially white, gradually becoming light brown and greenish when mature, regularly in reverse, petaloid at edge.

Maximum growth temperature. 30 °C.

Additional specimen examined. China • Hainan Province, Ledong County, Jianfengling National Forest Park (18.74540°N, 108.96716°E), from soil, 13 Oct 2023, M.F. Tao and X.Y. Liu, living culture XG06347D-2, SAUCC634702 or SAUCC6347D-2.

Notes. In the molecular phylogeny, *A. pateriformis* was closely related to *A. jiangxiensis*. Morphologically, the sporangiophores of *A. pateriformis* were at most four-wheeled and branched, while those of *A. jiangxiensis* were at most six-wheeled and unbranched. Additionally, the maximum length of the sporangiophores in *A. jiangxiensis* was significantly greater than that in *A. pateriformis* (156.5 μm vs 280.0 μm). The sporangia size was also smaller in *A. pateriformis* (16.8–30.6 × 11.2–26.7 μm vs 16.5–48 × 16.5–44 μm), with only one projection observed instead of two and a narrower columellae (8–21 μm vs 10–34 μm). Zygospores were not observed in *A. pateriformis* (Zhao et al. 2023).

Discussion

Absidia is predominantly distributed in soil environments (Richardson 2009). In this study, we investigated the soil in Hainan Province. Based on morphology, growth temperature dynamics and molecular phylogenetic analyses, we identified three novel species in the genus *Absidia*, namely *A. pacifica* sp. nov., *A. crystalloides* sp. nov., and *A. pateriformis* sp. nov. The inclusion of these three taxa altered the topology of the *Absidia* tree. Through joint data analysis of SSU, ITS, LSU, TEF-1α and *Act*, the placement of these new species in the evolutionary tree was robustly supported (*A. pacifica* 100% MLBV and 0.98 BIPP; *A. crystalloides* 100% MLBV and 1.00 BIPP; *A. pateriformis* 100% MLBV and 1.00 BIPP; Fig. 1). The phylogenetic analysis also revealed a close relationship between *A. pacifica* and *A. edaphica* (100% MLBV, 1.00 BIPP), whereas *A. crystalloides* exhibited a close affinity to both *A. oblongispora* and *A. heterospora* (100% MLBV, 1.00 BIPP), and *A. pateriformis* demonstrated a strong association with *A. jiangxiensis* (100% MLBV, 1.00 BIPP). Simultaneously, we observed certain variations in morphological structure and physiology, which served as the basis for species identification. The three newly discovered species and their related counterparts exhibited varying degrees of discrepancy in sporangiophores, sporangia, projections, sporangiospores, and other structures. Furthermore, the maximum growth

temperatures were found to be distinguishable among these species. These dissimilarities served as the foundation for the identification of novel species.

Currently, the phylogenetic analysis of *Absidia* primarily employed a combined analysis of SSU, ITS, LSU, TEF-1α, and *Act*. Previous studies demonstrated that due to the significant variation among *Absidia* species, relying solely on ITS for identifying *Absidia* species might yield inaccurate results; therefore, it was essential to incorporate LSU or other gene markers in the analysis process. Nucleotide sequences of SSU ITS, LSU, TEF-1α, and *Act* fragments served as robust tools for *Absidia* identification (White et al. 1990; Hoffmann et al. 2007, 2013; Ariyawansa et al. 2015).

Early on, *Lichtheimia* was initially classified as *Absidia* due to its morphological resemblance, Hoffmann et al. (2007) categorized *Absidia* into three groups based on their maximum growth temperature: thermotolerant (≥37 °C), mesophilic (25 °C–34 °C), and mycoparasitic (≤30 °C). The thermotolerant strains were subsequently reclassified as *Lichtheimia*. Currently, there were hardly any identified strains of *Absidia* capable of growing at a maximum temperature of 37 °C (Zhao et al. 2022b, 2023). This study further confirmed this conclusion by demonstrating that the maximum growth temperatures for *A. pacifica*, *A. crystalloides*, and *A. pateriformis* were 35 °C, 32 °C and 30 °C, respectively.

In China, the majority of *Absidia* species were predominantly distributed in Xinjiang, Taiwan, and Yunnan, primarily inhabiting tropical, subtropical, and temperate regions (Zhao et al. 2022b). However, due to its limited tolerance for high temperatures, most *Absidia* species found in tropical areas were typically restricted to cool and humid environments such as forest soil and dung (Cordeiro et al. 2020; Lima et al. 2021). The discovery of the three new species in this study was exclusively made in the tropical forest soil of Hainan Island. This finding further validated the remarkable species diversity of *Absidia* within tropical and subtropical regions while also providing valuable insights for future exploration into additional *Absidia* strains.

Abstract

Journal impact factors were devised to qualify and compare university library holdings but are frequently repurposed for use in ranking applications, research papers, and even individual applicants in mycology and beyond. The widely held assumption that mycological studies published in journals with high impact factors add more to systematic mycology than studies published in journals without high impact factors nevertheless lacks evidential underpinning. The present study uses the species hypothesis system of the UNITE database for molecular identification of fungi and other eukaryotes to trace the publication history and impact factor of sequences uncovering new fungal species hypotheses. The data show that journal impact factors are poor predictors of discovery potential in systematic mycology. There is no clear relationship between journal impact factor and the discovery of new species hypotheses for the years 2000–2021. On the contrary, we found journals with low, and even no, impact factor to account for substantial parts of the species hypothesis landscape, often discovering new fungal taxa that are only later picked up by journals with high impact factors. Funding agencies and hir-

ing committees that insist on upholding journal impact factors as a central funding and recruitment criterion in systematic mycology should consider using indicators such as research quality, productivity, outreach activities, review services for scientific journals, and teaching ability directly rather than using publication in high impact factor journals as a proxy for these indicators.

Key words: Bibliometrics, impact factor, mycology, systematics, taxonomy

Introduction

The concept of journal impact factors (IFs) was introduced in the 1970s as a means to qualify and compare university library holdings (Garfield 2006; Casadevall and Fang 2014). It was argued that since a journal's IF is computed as the average number of recent citations to papers recently published in that journal, the IF indicates the relative importance of that journal. IFs could thus be used as guidance for cost-efficient trimming of library holdings – and, by computing average IFs for entire libraries, for ranking libraries according to the perceived importance of their holdings. By and large, the IF concept was well received by the librarian community by virtue of offering some degree of objectivity in what up to that point had been a signally subjective enterprise (Archambault and Larivière 2009). However, it did not take long before the IF concept was invested with meaning and significance far beyond its intended jurisdiction and saw use to rank individual research papers and even researchers according to perceived importance (Simons 2008). A researcher's average or cumulative IF could be used, many hiring committees and research funding agencies started to argue, to rank candidates or applicants in a reasonably objective, and above all time- and cost-efficient, manner. Heavily laden with mystical import, the IF concept soon took a firm grip on the research landscape (McKiernan et al. 2019).

Over time, parts of the scientific community warmed to the idea that IFs may be an unwarrantably simplistic predictor of past and future research performance (Dong et al. 2005; Krell 2000; Lăzăroiu 2013). Indeed, there are countless examples of pivotal research papers that were published in journals with no, or low, or moderate impact factors – and substandard, faulty, or downright fraudulent papers published in high-IF journals (Trikalinos et al. 2008; Brembs 2018). But still, in the year 2024, the use of IFs as indicators of scientific performance and potential holds significant traction in the scientific community. Many of the present authors regularly serve in various evaluation committees for promotions, academic positions, and research grants in systematic mycology and beyond. In this capacity we are typically asked to rank applicants or applications in order of relevance to the matter at hand. We're instructed – and happy – to consider a multitude of parameters, including research performance, previous grants, stays abroad, time spent on parental leave, teaching, supervision, review services, and outreach. But often enough, when the committee finally convenes to negotiate a joint position, IFs tend to surface as the most decisive – and sometimes the only – parameter of relevance. The oracular emphasis laid on IFs at the expense of all other parameters is a perennial source of amazement to us. It effectively punishes researchers and research groups who ever spent any time doing anything other than maximizing IFs (Rushforth

and de Rijcke 2015; Johann et al. 2024). But is it really the case that mycological discovery scales in a linear way with impact factor so that by choosing the application/applicant with the highest impact factor statistics, we get the most mycology for the money? Several of us have struggled to look ourselves in the mirror following committee meetings of this kind.

In the context of systematic mycology, down-prioritizing researchers and research groups without a strong track record of high-IF publications would make sense if, indeed, low-IF publications and no-IF publications do not contribute much, or anything, to systematic mycology. Conversely, if it is the case that also (or even primarily) low- and no-IF publications make substantial contributions to this field, then the usefulness of IFs as a decisive indicator in systematic mycology would be illusory and, in fact, directly counterproductive. Is there data to form some sort of evidential underpinning for the contribution of IFs to systematic mycology? We argue that there is. The UNITE database for molecular identification of eukaryotes clusters all public, full-length fungal barcode (nuclear ribosomal internal transcribed spacer, or ITS) sequences in the International Nucleotide Sequence Database Collaboration (Arita et al. 2021) into roughly species-level entities referred to as species hypotheses (SHs; Abarenkov et al. 2024). These SHs can be thought of as digital twins of the underlying species, and meticulous record and rich metadata are kept for all sequences in each SH, including the publication history of each sequence. Theory can thus be pitted against experiment by querying the IF of the constituent sequences of SHs. Is it really the case that new species of fungi are primarily found in high-IF publications, for instance? And is the trend of IFs versus mycosystematical discovery linear, just like parts of the mycological community seem so happy to assume? Do scientific outlets without formal IFs really contribute nothing to mycology? The present study sets out to assess whether the reliance put on IFs in systematic mycology holds up to empirical scrutiny. Our results suggest that the use of IFs as arbiters of scientific quality and discovery potential in systematic mycology is not consistent with the image of rationality that we feel systematic mycology should seek to project.

Materials and methods

The full flow of operation behind the UNITE database is described elsewhere (Kõljalg et al. 2013, 2020; Abarenkov et al. 2024). In brief, UNITE clusters the ITS sequences of the International Nucleotide Sequence Database Collaboration (INSDC) jointly with UNITE-contributed environmental DNA (eDNA, DNA obtained from mixed/bulk samples) ITS sequences into species hypotheses at distance thresholds 0.5% through to 3.0% in steps of 0.5%. These operational taxonomic units can be thought of as entities roughly at the species level. The sequences and the SHs are available for web-based interaction as well as for download in various formats (https://unite.ut.ee/repository.php).

The 1,258,182 Sanger sequencing-derived sequences of UNITE eukaryotic release 10 were found to be distributed across 182,847 SHs at the default 1.5% sequence dissimilarity level. We targeted sequences submitted to the INSDC in the interval 2000–2021. All 43,057 non-singleton SHs whose first (earliest date of INSDC deposition) sequence was annotated (by default or by subse-

quent third-party sequence annotation) as fungal were targeted. These SHs comprised a total of 506,103 sequences. All other SHs were considered to represent non-fungal eukaryotes and are not treated any further in this study. We examined all sequences computationally for information on publication of origin. A total of 23,710 (55.1%) fungal SHs were first discovered through a sequence for which a published study of origin was specified in INSDC, leaving 19,347 (44.9%) of the initial-SH-discovery sequences with a publication status of the "Unpublished" or "Direct submission" kind. Some proportion of these seemingly unpublished sequences can be expected to be published but not updated with publication information in INSDC (Durkin et al. 2020). We thus subjected all 19,347 such seemingly unpublished sequences to manual Google and Google Scholar searches to see if they in fact had been published. In these queries, we used the INSDC accession number, the author names, and the title of the study (as available).

Official journal impact factors were compiled from ISI Web of Science for the period 2000–2021 for all journals sporting sequences in all SHs deemed to be fungal. The annual median impact factor for mycology was inferred from the 33 mycological journals in ISI's journal category "Mycology". Each sequence was assigned the impact factor of its outlet and the year of publication in the IF window 2000–2021. Two alternative approaches were adopted for sequences published in an outlet without a formal IF for the year of publication. In the "strict median" approach, they were not assigned any IF value and were excluded from estimates of median IFs. In the "relaxed median" approach, they were assigned an IF of 0.0 and were included in estimates of median IFs. IFs were considered down to the three decimal digits supported by ISI Web of Science. As a baseline, we also analyzed all formal fungal species descriptions 2000–2021 for impact factor using GBIF (https://www.gbif.org/) and MycoBank (Robert et al. 2013).

Results

We found 43,057 non-singleton UNITE SHs to be fungal. The first (oldest) sequence in each such SH was examined for publication information. More than half (23,710; 55.1%) of these were found to be annotated to publication of origin, leaving 19,347 (44.9%) of the "Unpublished" and "Direct submission" kind. We were able to track down 10,203 (52.7%) of these to a published study of origin, giving us a final dataset of 33,913 published sequences, each representing a first, initial discovery of an SH. These 33,913 sequences were found to come from 6,878 studies. Sequences only released through B.Sc./M.Sc./Ph.D. theses were scored as unpublished. The unpublished sequences are not considered any further in this study. The SH-derived sequences of the study were found to have been published in well over 1,500 different journals and outlets, ranging from top-tier international journals with an IF of over 30 to what seemed to be regional or even local journals without an online presence.

In total, 28,662 (84.5%) of the sequences that were the first to evince a new SH discovery were published in a scientific journal with a formal IF that year, leaving 5,251 (15.5%) of the sequences published in an outlet without. Out of those 5,251 sequences, 2,223 (42.3%) were published in a journal that did not have a formal IF at the time of publication, but that eventually obtained one af-

ter an average of 4.7 years, leaving 3,028 (57.7%) of the without-IF-sequences published in an outlet that never had a formal IF (2000–2021). The *strict* and *relaxed* median IFs of sequences discovering new SHs over time are displayed in Fig. 1a. Fig. 1b visualizes the difference between the strict/relaxed approaches and the median IF in mycology. Fig. 2 shows the proportion of SHs whose initial discovery was reported in a journal without a formal IF, and with an IF below the mycological median, respectively, over time. Fig. 3 provides a window on the IF trend inside SHs by plotting the IFs of subsequent recoveries of the SH following its initial discovery. To account for the trend of increasing IFs in mycology over time, the data in Fig. 3 was normalized by subtracting the median impact factor of the journals in ISI's category "Mycology".

11,386 (33.6%) SHs contained sequences that were released through two or more distinct studies, all of which either lacked a formal IF or had an IF below the median mycological IF the year of publication. Similarly, 2,048 (6.0%) SHs were found to be known from two or more distinct studies, all of which had an IF above the median mycological IF the year of publication. 313 (0.9%) SHs were found to be known from two or more distinct studies, none of which were published in an outlet with a formal IF. In analogy, 12,477 (36.8%) SHs were found to be known from two or more distinct studies, all of which were published in an outlet with a formal IF at the year of publication. 1,260 (3.7%) non-singleton SHs were recovered both from journals with and without formal IFs. The results of the analysis of the impact factors of formal fungal species descriptions 2000–2021 are given in Suppl. material 1.

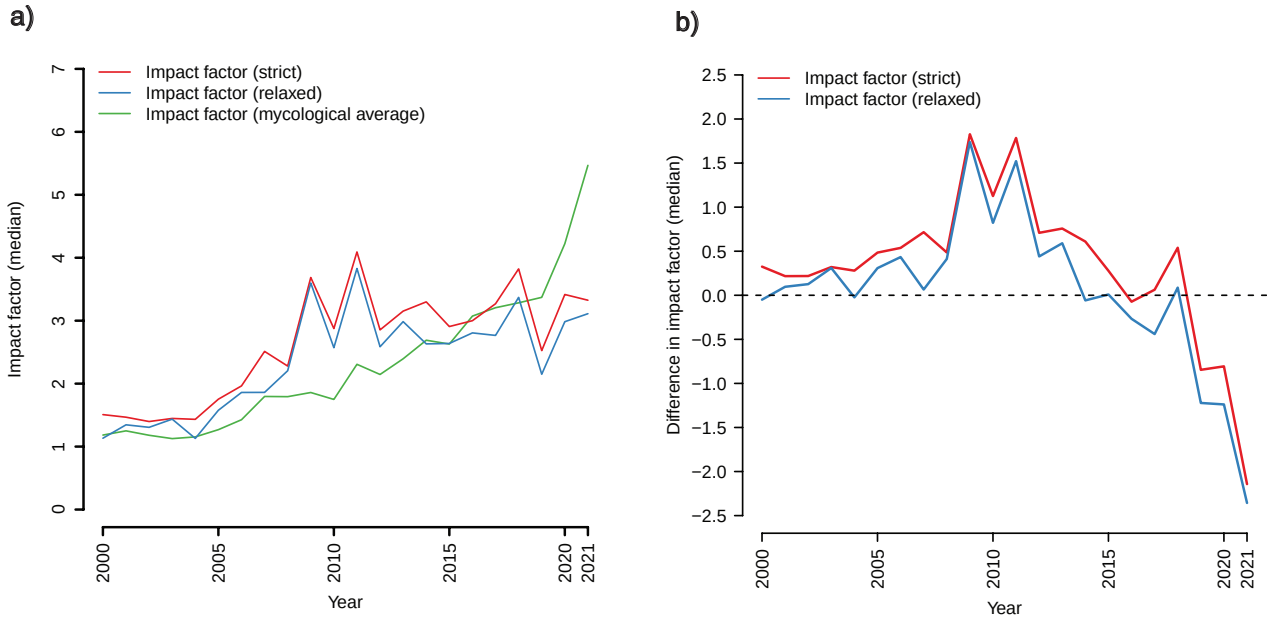

Figure 1. a the median impact factor of initial discoveries of UNITE species hypotheses (SHs). For the red curve, only sequences published in a journal with a formal impact factor from the year of publication were included in the calculation. For the blue curve, also sequences published in journals without a formal impact factor from the year of publication were included with their impact factor set to 0.0. The green curve shows the average impact factor of the journals in ISI's category "Mycology" over time **b** the median impact factor of initial discoveries of SHs visualized as the difference in IF from the median mycological IF (dashed line) over time. The post-2015 drop in relative impact factor is presumably explained by the trend of increasing IFs in ISI's category "Mycology" over time and mycologists' apparent struggle to take advantage of this trend when publishing.

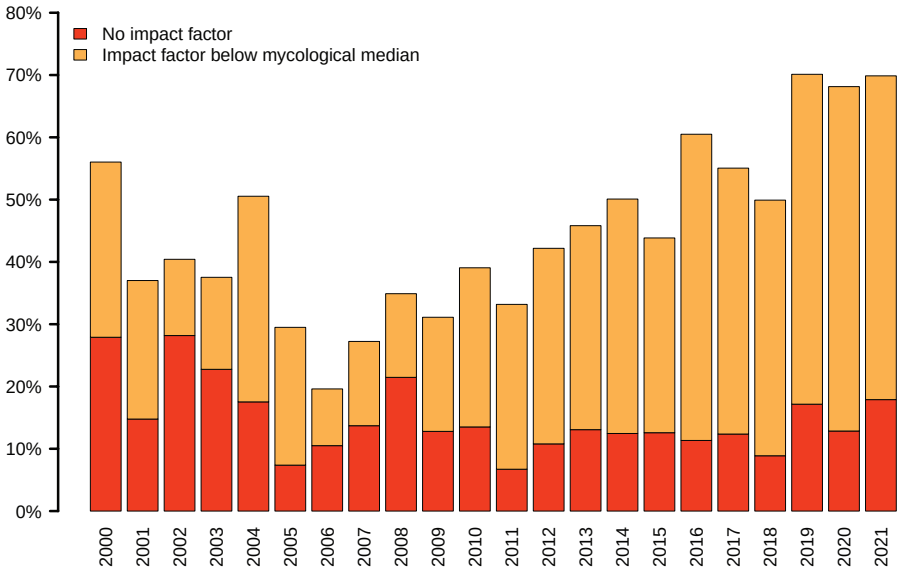

Figure 2. The proportion of SHs whose initial discovery was reported in a journal without a formal IF (red) or with an IF below the mycological median (orange) over time.

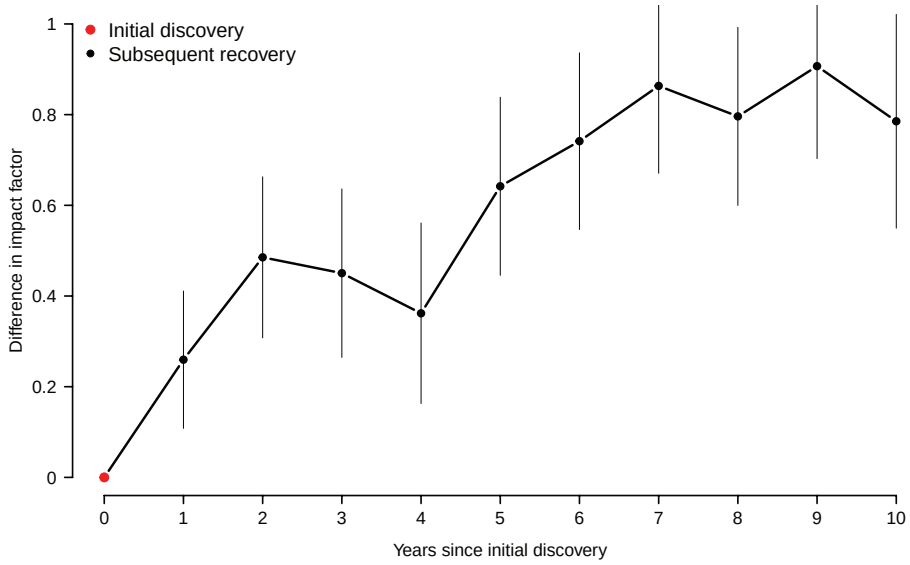

Figure 3. The median IFs of sequences inside SHs over time. SHs were discovered at year 0. The SHs were then inspected for subsequent recoveries in journals with a formal IF, and the value plotted is the median of all such recoveries. To account for the trend of increasing IFs in mycology, the data was normalized by subtracting the median impact factor of the journals in ISI's category "Mycology". The unit of the y axis is difference in IF. The error bars show 95% confidence intervals.

Discussion

The present study examined the relation of journal IFs to discovery potential in systematic mycology. Our results are largely dispiriting – there seems to be no meaningful correlation between IFs and mycosystematical discovery potential as measured as the discovery of new SHs in UNITE. On the contrary, at least in systematic mycology, journal IFs come across as a concept divested of meaning, or at least the meaning ascribed to it in the committee meetings that many of the present authors regularly attend. For instance, for the last 10 years, the majority of new SHs were first reported from journals with an IF below the median mycological IF in a trend that is accentuated over time (Fig. 2). Similarly,

formal description of species seems to be a perpetually below-median exercise (Suppl. material 1). In some sense this indicates that journals with an IF above the mycological median do not play an important role in systematic mycology, yet these high-IF journals are what we tend to put a premium on in mycosystematical committees, at least in our experience. The non-trivial proportion of SHs recovered only from no-IF and below-median-IF studies suggests that mycological research traditions and choices of taxonomic target groups differ widely – in fact, disparately – across and among those who study fungi in one capacity or another. Indeed, to some extent, different groups of fungi are studied in no/below-median-IF journals compared to above-median-IF journals. Suppressing mycological research published in no/low-IF outlets is thus tantamount to advocating a paraphyletic view of the fungal kingdom. Such a stance does not blend well with contemporary phylogenetic thinking, where wide and representative taxon sampling is identified as a non-negotiable cornerstone (e.g., Heath et al. 2008).

In an IF-centred world, important mycological findings would be announced in high-IF journals, and those results would only later trickle down and be subsumed into studies published in journals of lesser, or no, IFs. Our results take umbrage with such a contention (Fig. 3). Indeed, publications in high-IF journals seem to draw from the results of publications that were not published in high-IF journals in a way not usually considered in the committee meetings we attend. Figs 1–3 and Suppl. material 1 jointly suggest that the majority of non-trivial discoveries in systematic mycology – particularly in recent years – are being presented in journals that can be called "below average" or even "objectionable" in the sense of lacking a formal IF altogether. That makes – it seems to us – the practice of prioritizing "above average" journal publications in committee situations inimical to systematic mycology. Clearly, journal IFs and species discovery make uneasy bedfellows. The discovery and description of new species are essential for laying the groundwork for scientific progress, yet they do not necessarily resonate well with the short timeframe for IFs and the criteria used by high-IF journals for publication.

Our results do not necessarily suggest that the mycological community should prioritize low/no-IF researchers and research teams, but rather that IFs are a superficially deep, but deeply superficial, measure of mycosystematical discovery potential. If it, indeed, is mycosystematical discovery potential that we wish to promote, then time's provision of further and better particulars seems to call for abandoning oversimplified shortcuts in the assessment of a researcher's previous production. Maybe, in fact, there are no shortcuts (Bertuzzi and Drubin 2013). Maybe committees really have to go through a few of the applicants' main papers in detail to assess the quality and the scientific explanatory power of their findings. Maybe the committee really needs to examine and compare the citations to each individual paper to further quantify and qualify the import of those papers on mycology. And maybe the proposed research project will have to be given more than fleeting attention after all. That would clearly be a very time-consuming approach – presumably a horrifying thought to many, the present authors included. This is, nevertheless, what our results seem to suggest.

Ranking candidates based on IFs furthermore perpetuates the 'Matthew effect' whereby candidates who happen to publish in high impact journals early in

their career accrue more recognition and cumulative advantage relative to other candidates (Petersen et al. 2011; Rushforth and de Rijcke 2015). This is problematic when candidates have early career advantages not directly related to their research potential. Given many institutions' commitments to Diversity, Equity, and Inclusion (DEI), the elimination of IF-bias in highly specialized fields where this metric has been shown to be a poor indicator of research contributions should be a priority. The self-correcting nature of science reflects openness to revision when new data come to light, something that we feel should apply also to the evaluation of science. Considering our work and others, committees that insist on making decisions that are heavily weighted by IFs should also consider the risk of bias entrenched in current processes (Boutron et al. 2023).

This study makes the simplification to define "systematic mycology" as the field that discovers and describes new species and groups of fungi – which is what the present study quantifies. We are well aware that systematic mycology covers more than just that, and that the discovery of new SHs in UNITE and formal description of species do not do full justice to the discipline. At the same time, it would seem like a stretch to argue that the discovery and formal description of new species and groups of fungi, unlike all other aspects of systematic mycology, scale poorly to IFs. Instead, we hypothesize that our data speak reasonably well for all of systematic mycology in arguing against the use of IFs as a decisive indicator in systematic mycology. Our study made heavy use of the UNITE SH system, which is based on the formal fungal barcode, the nuclear ribosomal ITS region (Schoch et al. 2012). While we agree that the ITS region is by all accounts the best choice of a singular fungal barcode, it is nevertheless a genetic marker that does not reflect species boundaries perfectly throughout the fungal kingdom (Abarenkov et al. 2016). We used the dynamic SH release of UNITE in an attempt at avoiding the use of static similarity thresholds for automated designations of operational taxonomic units, but it is inevitable that some degree of taxonomic artificiality marks our results (Nilsson et al. 2019).

Our approach was to some extent haunted by missing data – at the onset of the project, a full 19,347 (44.9%) of the sequences representing initial discoveries of species hypotheses were not annotated with a study of origin. We spent more than three months trying to restore this information, but we often found ourselves struggling with journals without a digital presence, journals in other languages than the present set of co-authors had access to, special characters, conflicting information, and the sheer magnitude of the task at hand. In the end, we were able to restore the publication information for 10,203 sequences, reducing the share of "unpublished" sequences from 49.7% to 21.2%. We find it remarkable that upwards of half of the public fungal barcode sequences older than two years were un-annotated to begin with in this regard. Durkin et al. (2020) provided data to suggest that systematic mycology does not maximize its scientific and outreach potential, and the present study lends further weight to those claims. Another source of bias in our results comes from our decision to target only the INSDC and Sanger-sequencing-derived sequences in UNITE. In addition to these sequences, UNITE also features five very large metabarcoding datasets published in high-profile journals (Nilsson et al. 2023). We felt that if we were to also include metabarcoding studies in our approach, then we would have to include not just five high-profile – but all extant – metabarcoding studies to get an unbiased view. However, there is no centralized resource

where all metabarcoding datasets are available in an accessible way, and the prospects for clustering billions or even trillions of sequences into the UNITE SH system would furthermore have been bleak. The present paper thus reflects the Sanger sequencing view of systematic mycology.

Conclusion

Mycologists regularly report feeling compelled to publish in high-IF journals by virtue of professionalism. Our data suggest that if we by professionalism mean keeping the best interest of systematic mycology in mind, then journal IFs are at a particular risk of misinterpretation – and are regularly ascribed a weight that endangers progress in the field. We eagerly anticipate a future where applications and candidates are assessed in a more integrative way than simple summary metrics obtained from journal IFs, and where mycological contributions are quantified in a way agnostic of the very journal in which they happened to be published. Our non-trivial experience of serving in various evaluation committees is dispiriting in this regard, painting a bleak picture for the future of systematic mycology in a time when the understanding of fungal diversity is more important than ever.

Abstract

Gongronella had accommodated only two species for more than half a century and as many as 17 new species have been described in this genus since 2015. However, no systematic studies were conducted for this genus so far. The distribution, substrate and morphology of all known species in *Gongronella* are analysed herein. Meanwhile, with the support of phylogenetic and morphological evidence, six new species (*G. abortosporangia* **sp. nov.**, *G. apophysata* **sp. nov.**, *G. bawanglingensis* **sp. nov.**, *G. inconstans* **sp. nov.**, *G. pingtangensis* **sp. nov.** and *G. reniformis* **sp. nov.**) are proposed and *G. pamphilae* is recorded from China for the first time. The phylogenetic tree was constructed using ITS+LSU+TEF+ACT+RPB1 and the results were basically the same as ITS+LSU. All species of *Gongronella*, except *G. namwonensis* from fresh water, were isolated from soil. The genus is distributed worldwide, mainly in tropical and subtropical regions. A synoptic key is provided for a total of 24 species (18 species previously published and six species newly described herein), except for *G. banzhaoae* due to unavailable protologue, type and living culture. No morphologies were described when *G. pamphilae* was proposed. Thanks to the strains isolated in this study, *G. pamphilae* is included in the key and reported as a Chinese new record. This is the first comprehensive taxonomy and phylogeny of the genus *Gongronella*.

Key words: Mucoromycota, molecular phylogeny, new taxa, soil-borne fungi, taxonomy

Introduction

The genus *Gongronella* Ribaldi has a great potential in biological applications due to the ability of producing bioactive substance such as chitosan (Wang et al. 2008; Zhou et al. 2008), dissolving phosphate and degrading metalaxyl (Doilom et al. 2020; Martins et al. 2020). *Gongronella* sp. w5, a well-known strain in this genus, can induce fungi *Panus rudis* (Wei et al. 2010) and *Coprinopsis cinerea* (Pan et al. 2014; Hu et al. 2019; Liu et al. 2022) to produce laccase, secrete organic acids for improving the acquisition of phosphate in plants and thus promote their growth (Dong et al. 2018; Wang et al. 2021) and synthesise various bioactive enzymes, such as β-glucosidase and invertase (Zhou et al. 2020; Mai et al. 2021).

This genus was established in 1952 and typified with *Gongronella urceolifera* Ribaldi (Ribaldi 1952). It belongs to Mucoromycota Doweld, Mucoromycetes Doweld, *Mucorales* Dumort, Cunninghamellaceae Naumov ex R.K. Benj. (Tedersoo et al. 2018). Before 2015, the taxonomy of *Gongronella* was stagnant, accommodating only two species *G. urceolifera* (= *G. butleri*) and *G. lacrispora*. Since 2015, as many as 17 species have been described successively (Hesseltine and Ellis 1961; Adamcik et al. 2015; Ariyawansa et al. 2015; Li et al. 2016; Tibpromma et al. 2017; Dong et al. 2019; Zhang et al. 2019; Crous et al. 2020; de Freitas et al. 2020; Doilom et al. 2020; Martins et al. 2020; Wang et al. 2023a; Zhao et al. 2023). At present, *Gongronella* contains 19 species, nearly half of which were initially found from China (Table 1). In the GlobalFungi database, there are a total of 3,039 sample records for the genus *Gongronella* covering Asia (1,566, 51.53%), North America (571, 18.79%), Europe (433, 14.58%), South America (261, 8.59%), Africa (123, 4.05%), Australia (64, 2.11%) and Atlantic Ocean (1, 0.03%) (https://globalfungi.com/, accessed on 18 October 2024). Considering geographical climate, most samples were collected from tropical and subtropical regions (https://globalfungi.com/, accessed on 17 October 2024). In conclusion, the species of *Gongronella* were distributed worldwide and mainly concentrated in tropical and subtropical regions in Asia.

Regarding substrate of nomenclatural types within the genus *Gongronella*, *G. namwonensis* was isolated from fresh water and the other 18 species were all isolated from soil (Crous et al. 2020; Doilom et al. 2020). According to the GlobalFungi database, substrates include soil (1852, 60.94%), topsoil (475, 15.63%), root (403, 13.26%), rhizosphere soil (204, 6.71%), root + rhizosphere soil (52, 1.71%), litter (22, 0.72%), sediment (10, 0.33%), shoot (9, 0.3%) and deadwood (7, 0.23%), (https://globalfungi.com/, accessed on 19 October 2024). Although the GlobalFungi database showed more kinds of substrates of *Gongronella*, most strains were still isolated from a variety of soil samples.

In this study, 14 strains of the genus *Gongronella* were isolated from soil in Hainan, Yunnan, Sichuan and Guizhou Provinces from China. According to ITS+LSU+TEF+RPB1 molecular phylogenetic analyses and morphological comparisons, these strains were classified into six new species and one was identified as new record species to China. The morphological information of all described species of *Gongronella* was reviewed and compared.

Table 1. The origin of taxonomic types in *Gongronella*.

Countries	Type numbers	Percentage (%)

Materials and methods

Isolation and morphology

Soil samples were collected in Hainan Province (April 2023 and October 2023), Sichuan Province (June 2023) and Guizhou Province (August 2023). Strains were isolated from the soil samples by a combination of soil dilution and single spore isolation.

About 1 g soil sample was mixed with 10 ml sterile water to prepare 10^{-1} soil suspension. One millilitre of 10^{-1} suspension was transferred to 9 ml of sterile water to obtain a 10^{-2} soil suspension. In the same way, 10^{-3} and 10^{-4} soil suspensions were made. The final 10^{-3} and 10^{-4} soil suspensions (200 ml) were pipetted on the surface of Rose-Bengal Chloramphenicol Agar (RBC: peptone 5.00 g/l, glucose 10.00 g/l, KH_2PO_4 1.00 g/l, $MgSO_4 \cdot 7H_2O$ 0.50 g/l, rose red 0.05 g/l, chloramphenicol 0.10 g/l, agar 15.00 g/l) (Corry et al. 1995), dispersed evenly with sterilised coating rods and cultured at 25 °C in the dark for 2–5 days. Upon colonies were visible, they were transferred onto Potato Dextrose Agar (PDA: glucose 20.00 g/l, potato 200.00 g/l, agar 20.00 g/l, pH 7). When sporangia were produced, sporangiospores were suspended with sterile water and streaked with a sterilised inoculation ring. The plates were cultured at 25 °C in darkness and single spore colonies were transferred on to a new PDA plate for subculturing. To ensure the formation of zygospores, pairing experiments were carried out by adding 0.1% lecithin to PDA and sealing Petri dishes to retain moisture. The microscopic morphological characteristics of fungi were observed with an optical microscope (Olympus BX53) and photographed with a high-definition colour digital camera (Olympus DP80). All strains were stored with 10% sterilised glycerine at 4 °C. Each morphological character was statistically calculated from 30 measurements (Zhang et al. 2022). Cultures were deposited in the China General Microbiological Culture Collection Center, Beijing, China (CGMCC) and the Shandong Agricultural University Culture Collection, Taian, China (SAUCC). Specimens were deposited in the Herbarium Mycologicum Academiae Sinicae, Beijing, China (HMAS). Taxonomic information for the new taxa was registered in the Fungal Name repository (https://nmdc.cn/fungalnames/).

DNA extraction and amplification

Genomic DNA was extracted from mycelia using the CTAB method and BeaverBeads Plant DNA Kit (Cat. No.: 70409-20; BEAVER Biomedical Engineering Co., Ltd.) (Doyle et al. 1990; Guo et al. 2000; Wang et al. 2023b). ITS, LSU, TEF, ACT and RPB1 were amplified by polymerase chain reaction using ITS4/ITS5, LR0R/LR7, EF1-728F/EF1-986R, ACT-512F/ACT-783R and RPB1-Af/RPB1-Cr primer pairs, respectively (Table 2). Amplification was performed in a final volume of 20 µl, containing 10 µl 2× Hieff Canace® Plus PCR Master Mix (Yeasen Biotechnology, Cat No. 10154ES03), 0.5 µl of forward and reverse primers each (10 µM) (TsingKe, Beijing, China), 1 µl template genomic DNA (about 1 µM) and 8 µl distilled deionised water. Molecular loci, PCR primers and programmes used in this study are listed in Table 2. The PCR products were electrophoresed with 1% agarose gel. The DNA fragments were stained with GelRed and observed under

ultraviolet light. Then a gel extraction kit (Cat# AE0101-C; Shandong Sparkiade Biotechnology Co., Ltd.) was used for gel recovery. Sanger sequencing was carried out by Biosune Company Limited (Shanghai, China). Consensus sequences were assembled using MEGA v.7.0 (Kumar et al. 2016). All sequences generated in this study were deposited at GenBank under the accession numbers in Table 3.

Relative sequences were obtained by BLAST search in the GenBank nucleotide database of NCBI website (Kumar et al. 2016). Sequences both generated herein and retrieved from GenBank (Table 3) were aligned using MAFFT 7 online service (http://mafft.cbrc.jp/alignment/server/, 20 October 2023) (Katoh et al. 2019). The ITS, LSU, TEF, ACT and RPB1 sequences were analysed individually and jointly. The optimal evolutionary model for each partition was determined and included in the analysis using MrModelTest v.2.3 (Nylander 2004). Phylogenetic history was reconstructed using Maximum Likelihood (ML) algorithm with RaxML-HPC2 on XSEDE 8.2.12 (Stamatakis 2014; Zhao et al. 2024) and Bayesian Inference (BI) algorithm with MrBayes 3.2.7a (Huelsenbeck and Ronquist 2001; Ronquist and Huelsenbeck 2003; Ronquist et al. 2012). ML was performed for 1,000 bootstrap replicates with the GTRGAMMA model of nucleotide evolution. BI was performed using a quick start algorithm with an automatic stop option. The Bayesian analysis consisted of 5,000,000 generations with four parallel runs with the option of stopping rules and a sampling frequency of 100 generations. The burn-in score was set to 0.25 and the posterior probability (PP) was determined from the remaining trees. Initial adjustments of phylogenetic trees were made using FigTree v.1.4.4 (http://tree.bio.ed.ac) and the layout of the trees was finished using Adobe Illustrator CC 2019 (https://adobe.com/products/illustrator).

Results

Phylogenetic analyses

The sequence matrix included 43 strains in 25 species of *Gongronella*, with *Cunninghamella echinulata* CBS 156.28 as outgroup. A total of 4,080 characters comprised ITS rDNA (1–989), LSU rDNA (990–1967), TEF (1968–2172), ACT (2173–2948) and RPB1 (2949–4080). Amongst these characters, 2,866 were constant, 562 variable, but parsimony non-informative and 652 parsimony

Notes: New species established in this study are in bold. Ex-type or ex-holotype strains are labelled with a star mark "*". The abbreviation "n.a." stands for "not available"

informative characters (Suppl. material 1). MrModelTest suggested that the Dirichlet fundamental frequency and GTR+I+G evolution pattern for both partitions were adopted in Bayesian Inference. The topology of the Bayesian tree was consistent with that of the ML tree and, therefore, was used as a representative to summarise the evolutionary history within the genus *Gongronella* (Fig. 1). *G. abortosporangia* was closely related to *G. multiramosa* with a high support (BIPP = 0.95). *G. pingtangensis* was closely related to *G. namwonensis* with a high support (BIPP = 1). *G. reniformis* was closely related to *G. pamphilae* and *G. brasiliensis* with a high support (MLBV = 75, BIPP = 0.99). The *G. bawanglingensis* (MLBV = 100, BIPP = 1) is closely related to *G. qichaensis* and *G. inconstans*. *G. inconstans* (MLBV = 99, BIPP = 1) is closely related to *G. qichaensis* with a high support (BIPP = 0.96). *G. apophysata* is closely related to *G. zunyiensis*.

Taxonomy

Gongronella abortosporangia **Yi Xin Wang, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571253
Fig. 2

Etymology. The epithet "*abortosporangia*" (Latin) refers to the abortive sporangia.

Type. China • Hainan Province, Lingshui Li Autonomous County, Qixian Yaochi Yexi Hot Spring (18.70161°N, 109.69318°E), from soil sample, 10 April 2023, Yi-Xin Wang (holotype HMAS 352726, ex-holotype strain CGMCC 3.27028).

Description. Colonies growing slowly on PDA in darkness at 25 °C, reaching 49.2–52.4 mm in diameter in seven days, white, regular at edge and cottony in the centre, reversely milky white. Rhizoids hyaline, branched, irregularly shaped, with oil droplets. Stolons absent. Sporangiophores on aerial mycelia, erect or slightly curved, unbranched or branched (1–6 times), 4.0–96.8 × 1.0–4.2 µm, hyaline, smooth, mostly aseptate, sometimes one-septate and rarely two-septate, occasionally containing a line of oil droplets. Sterile (aborted) sporangia abundant, mainly on the top of short lateral branches of sporangiophores, mostly gourd-shaped, 11.6–16.7 × 5.5–17.7 µm, partially elliptical with a slight shrinkage, 12.5–18.0 × 6.7–10.6 µm, occasionally clavate, 20.1–22.7 × 9.5–10.4 µm. Fertile sporangia hyaline or light yellow, spherical, 7.0–23.2 µm in diameter, smooth and deliquescent-walled, leaving a collar after releasing sporangiospores. Columellae mostly hemispherical, 2.5–4.2 × 3.6–7.4 µm, sometimes sub-hemispherical, 1.3–3.9 × 3.6–5.5 µm, hyaline, smooth. Apophyses hyaline, smooth, variously shaped, mostly cup-shaped, 1.9–8.6 × 2.1–6.7 µm, partially hemispherical, 2.7–5.5 × 2.8–7.4 µm, occasionally pear-shaped, 8.2 × 7.2 µm. Sporangiospores not uniform, hyaline, smooth, ovoid, 2.6–3.5 × 1.7–2.1 µm, reniform, 2.9–3.5 × 1.7–2.3 µm. Chlamydospores gourd-shaped, 20.3–29.3 × 6.4–9.3 µm. Giant cells intercalary, globular, subglobular, 2.6–4.6 µm in diameter. Zygospores not found.

Additional specimen examined. China • Hainan Province, Lingshui Li Autonomous County, Benhao Town (18.70161°N, 109.69318°E), from soil sample, 10 April 2023, Yi-Xin Wang (living culture SAUCC 4064-2).

GenBank accession numbers. CGMCC 327028 (ITS, PP195847; LSU, PP195948; TEF, PP850088; ACT, PP933938; RPB1, PP842883), SAUCC 4064-2 (ITS, PP195848; LSU, PP195949; TEF, PP850089; ACT, PP933939; RPB1, PP842882).

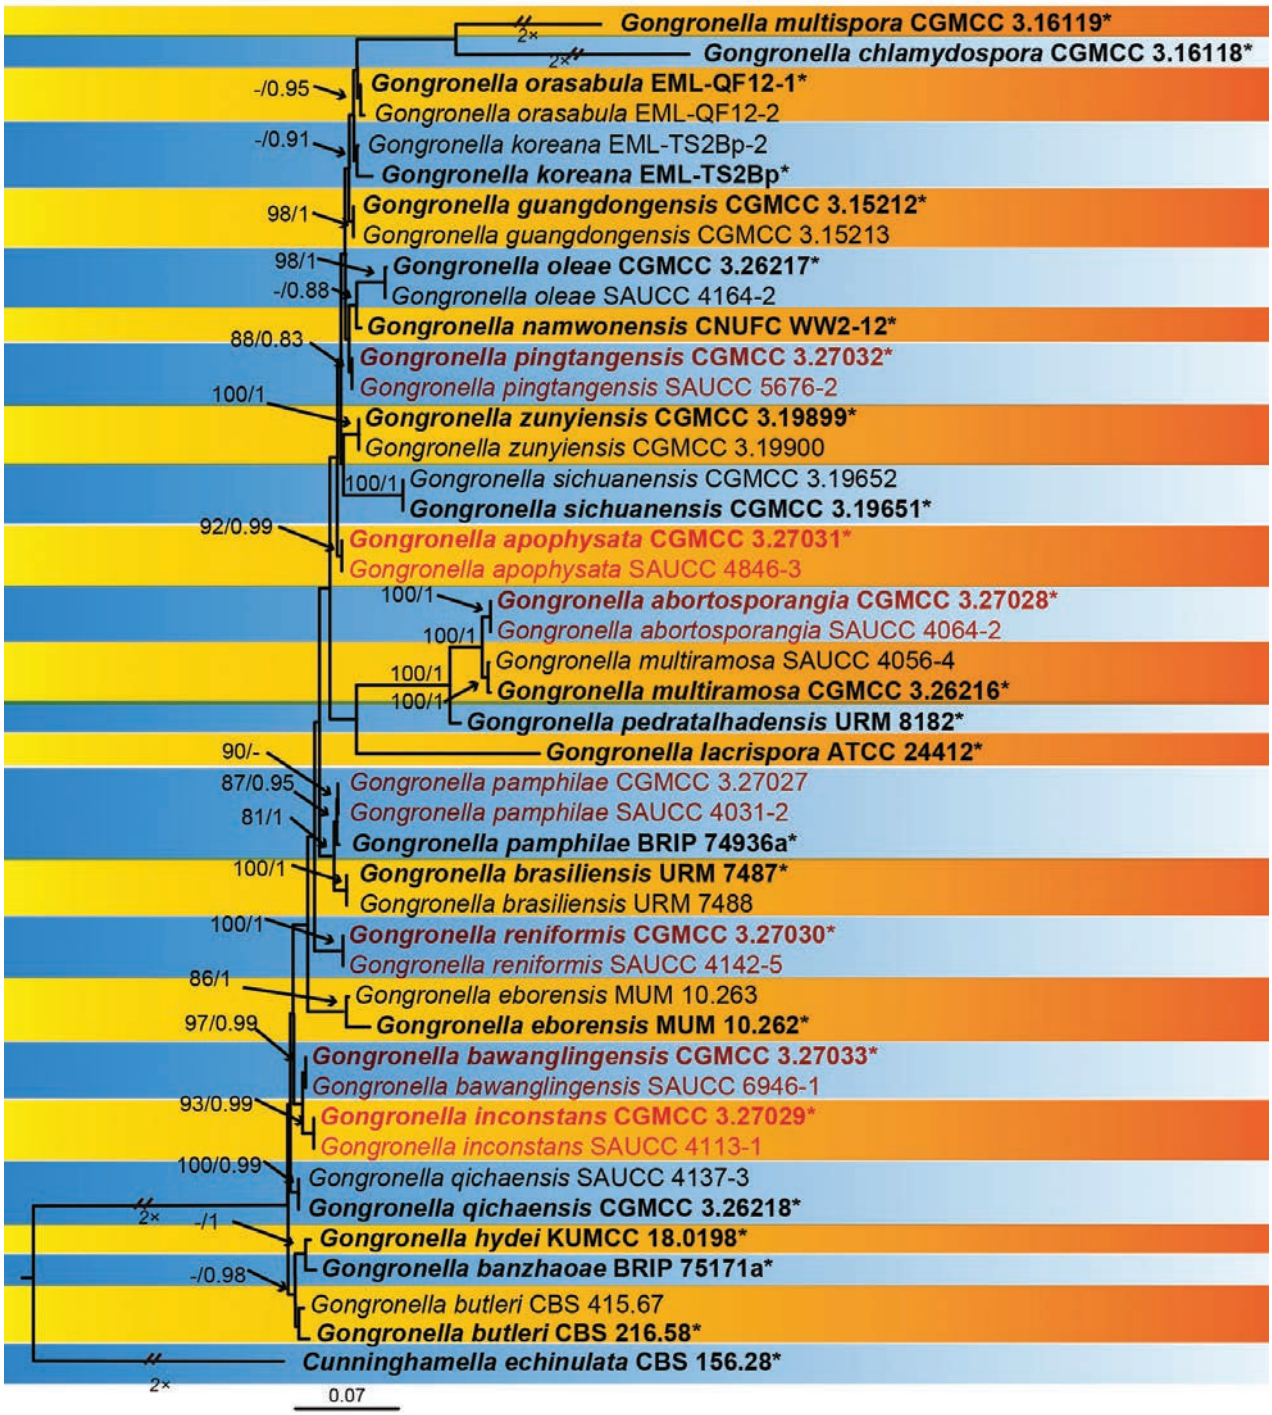

Figure 1. A Maximum Likelihood (ML) phylogenetic consensus tree inferred from DNA sequences of ITS, LSU, TEF, ACT and RPB1, showing relationships amongst species of *Gongronella* with *Cunninghamella echinulata* CBS 156.28 as outgroup. The Maximum Likelihood bootstrap value (MLBV) and Bayesian Inference posterior probability (BIPP) are successively shown at the nodes and separated by a slash "/". Strains marked with a star "*" are ex-types or ex-holotypes. The strains isolated and sequenced in this study are shown in red. Branches shortened to fit the page are represented by double slashes "//" and folds "×". The scale in the bottom centre indicates 0.2 substitutions per site.

Notes. Based on phylogenetic analyses of ITS+LSU+TEF+ACT+RPB1 sequences, the two isolates of the new species *Gongronella abortosporangia* formed an independent clade with high supports (MLBV = 100; Fig. 1), which is closely related to *G. multiramosa* (BIPP = 0.95; Fig. 1). This new species differs morphologically

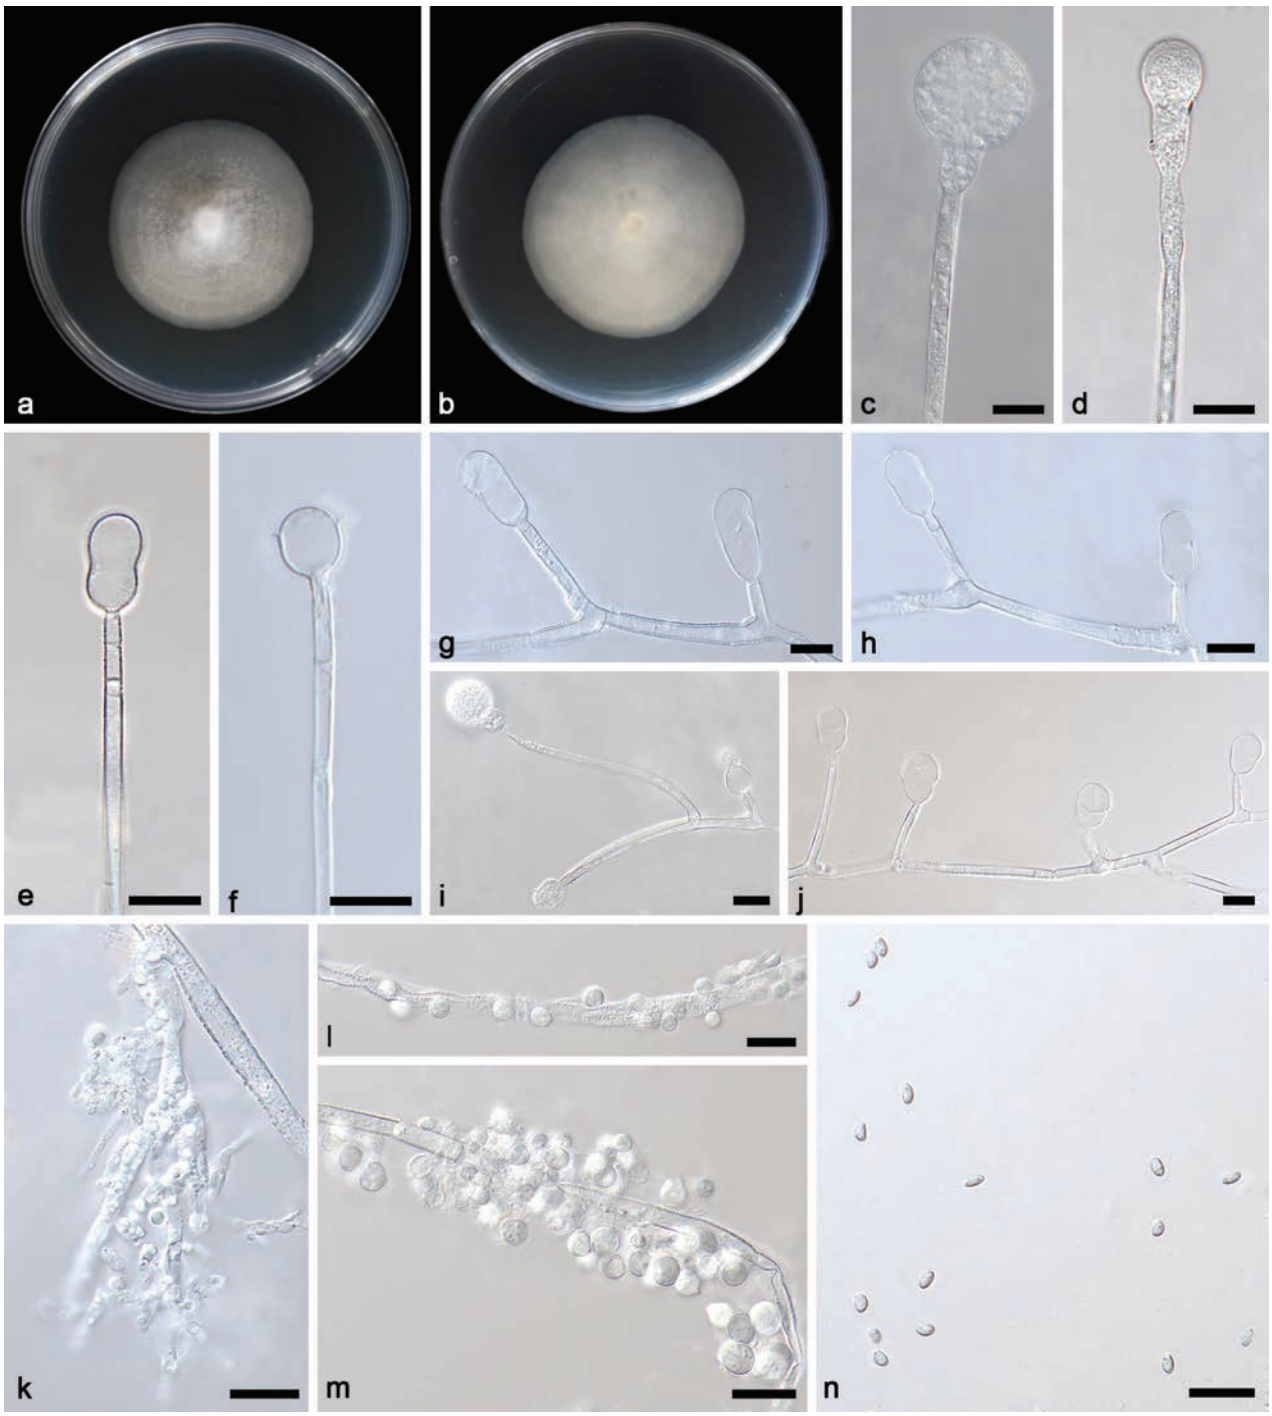

Figure 2. *Gongronella abortosporangia* ex-holotype CGMCC 3.27028 **a**, **b** colonies on PDA (**a** obverse **b** reverse) **c** an unbranched sporangiophore with a mature sporangium **d** an unbranched sporangiophore with an immature sporangium **e** an aborted sporangium with two septa **f** columellae, collars and apophyses **g**, **h**, **j** branched sporangiophores with sterile (aborted) sporangia **i** a branched sporangiophore with a mature sporangium, columellae, collars and apophyses **k** rhizoids **l**, **m** giant cells **n** sporangiospores. Scale bars: 10 µm (**c–n**).

from *G. multiramosa* in sporangium, septum, columella, collar and apophysis (Wang et al. 2023a). The *G. abortosporangia* is different from *G. multiramosa* in shape and size of sterile sporangia, the former being variously shaped, mostly gourd-shaped, 11.6–16.7 × 5.5–17.7 µm, partially elliptical with a slight shrinkage, 12.5–18.0 × 6.7–10.6 µm, occasionally clavate, 20.1–22.7 × 9.5–10.4 µm, while

the latter being only ovoid, 9.6 × 6.2 µm in diameter. In fertile sporangia, *G. abortosporangia* has a smaller minimum diameter than *G. multiramosa* (7.0 µm vs. 15.5 µm). *G. abortosporangia* has more septa on sporangiophores compared to *G. multiramosa* (0–2 vs. 0–1). Although *G. abortosporangia* is similar in shape of columellae to *G. multiramosa*, it is shorter in length (hemispherical, 3.6–7.4 µm vs. 8.0–9.8 µm, sub-hemispherical, 3.6–5.5 µm vs. 7.6–10.0 µm). The *G. abortosporangia* has shorter collars than *G. multiramosa*, 0.6–3.9 µm vs. 1.3–7.2 µm. The *G. abortosporangia* is similar in shape of apophyses to *G. multiramosa*. However, they are different from each other in main pattern and size: The former mostly cup-shaped (1.9–8.6 × 2.1–6.7 µm vs. 4.6–7.0 × 8.5–10.0 µm) and partially hemispherical (2.7–5.5 × 2.8–7.4 µm vs. 4.4–5.6 × 8.5–9.0 µm) and the latter opposite. Combining morphological and molecular phylogenetic analyses, we classified the two isolates as a new species *G. abortosporangia* allied to *G. multiramosa*.

***Gongronella apophysata* Yi Xin Wang, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571631
Fig. 3

Etymology. The epithet "*apophysata*" (Latin) refers to various shapes of apophyses.

Type. China • Sichuan Province, Emeishan City, Leshan City, Ehong Road, near the Xu family residence (29.59211°N, 103.37776°E), from soil sample, 25 June 2023, Yi-Xin Wang (holotype HMAS 352728, ex-holotype strain CGMCC 3.27031).

Description. Colonies growing slowly on PDA in darkness at 25 °C, reaching 35.8–42.4 mm in diameter in seven days, white, irregular at edge and cottony in the centrr, reversely milky white. Rhizoids hyaline, branched, irregularly shaped. Stolons absent. Sporangiophores on aerial mycelia, erect or slightly curved, unbranched or slightly branched (1–2 times), 11.2–190.9 × 1.6–3.9 µm, hyaline, smooth, mostly aseptate or one-septate, occasionally two-septate. Sterile (aborted) sporangia predominantly on the top of short lateral branches of sporangiophores, gourd-shaped, 14.0 × 8.3 µm. Fertile sporangia hyaline or light yellow, spherical, 12.5–40.5 µm in diameter, smooth and deliquescent-walled, leaving a collar after releasing sporangiospores. Columellae elliptic, 2.6–4.0 × 2.1–5.5 µm, sub-hemispherical, 1.4–2.7 × 2.2–4.3 µm, hyaline, smooth. Apophyses hyaline, smooth, variously shaped, mostly ellipsoidal to olive-shaped, 2.3–17.3 × 2.4–10.0 µm, partially subglobose, 4.6–10.2 × 4.3–10.0 µm, occasionally gourd-shaped, 11.4 × 4.9 µm. Sporangiospores not uniform, hyaline, smooth, mostly reniform, 3.2–5.5 × 1.7–3.1 µm, ovoid, 2.5–3.7 × 1.7–2.6 µm, occasionally subglobose, 1.7–2.5 µm. Chlamydospores present, not uniform, gourd-shaped, ellipsoidal and suborbicular, mostly gourd-shaped, 23.5–35.4 × 10.8–14.0 µm, partially ellipsoidal, 18.6–21.4 × 10.3–18.5 µm. Giant cells in the rhizoids, intercalary, globose, 4.4–10.5 µm in diameter. Zygospores not found.

Additional specimen examined. China • Sichuan Province, Emeishan City, Leshan City, Ehong Road, near the Xu family residence (29.59211°N, 103.37776°E), from soil sample, 25 June 2023, Yi-Xin Wang (living culture SAUCC 4846-3).

GenBank accession numbers. CGMCC 3.27031 (ITS, PP195853; LSU, PP195954; TEF, PP850099; ACT, PP933947; RPB1, PP842878), SAUCC 4846-3 (ITS, PP195854; LSU, PP195956; TEF, PP850100; ACT, PP933948; RPB1, PP842877).

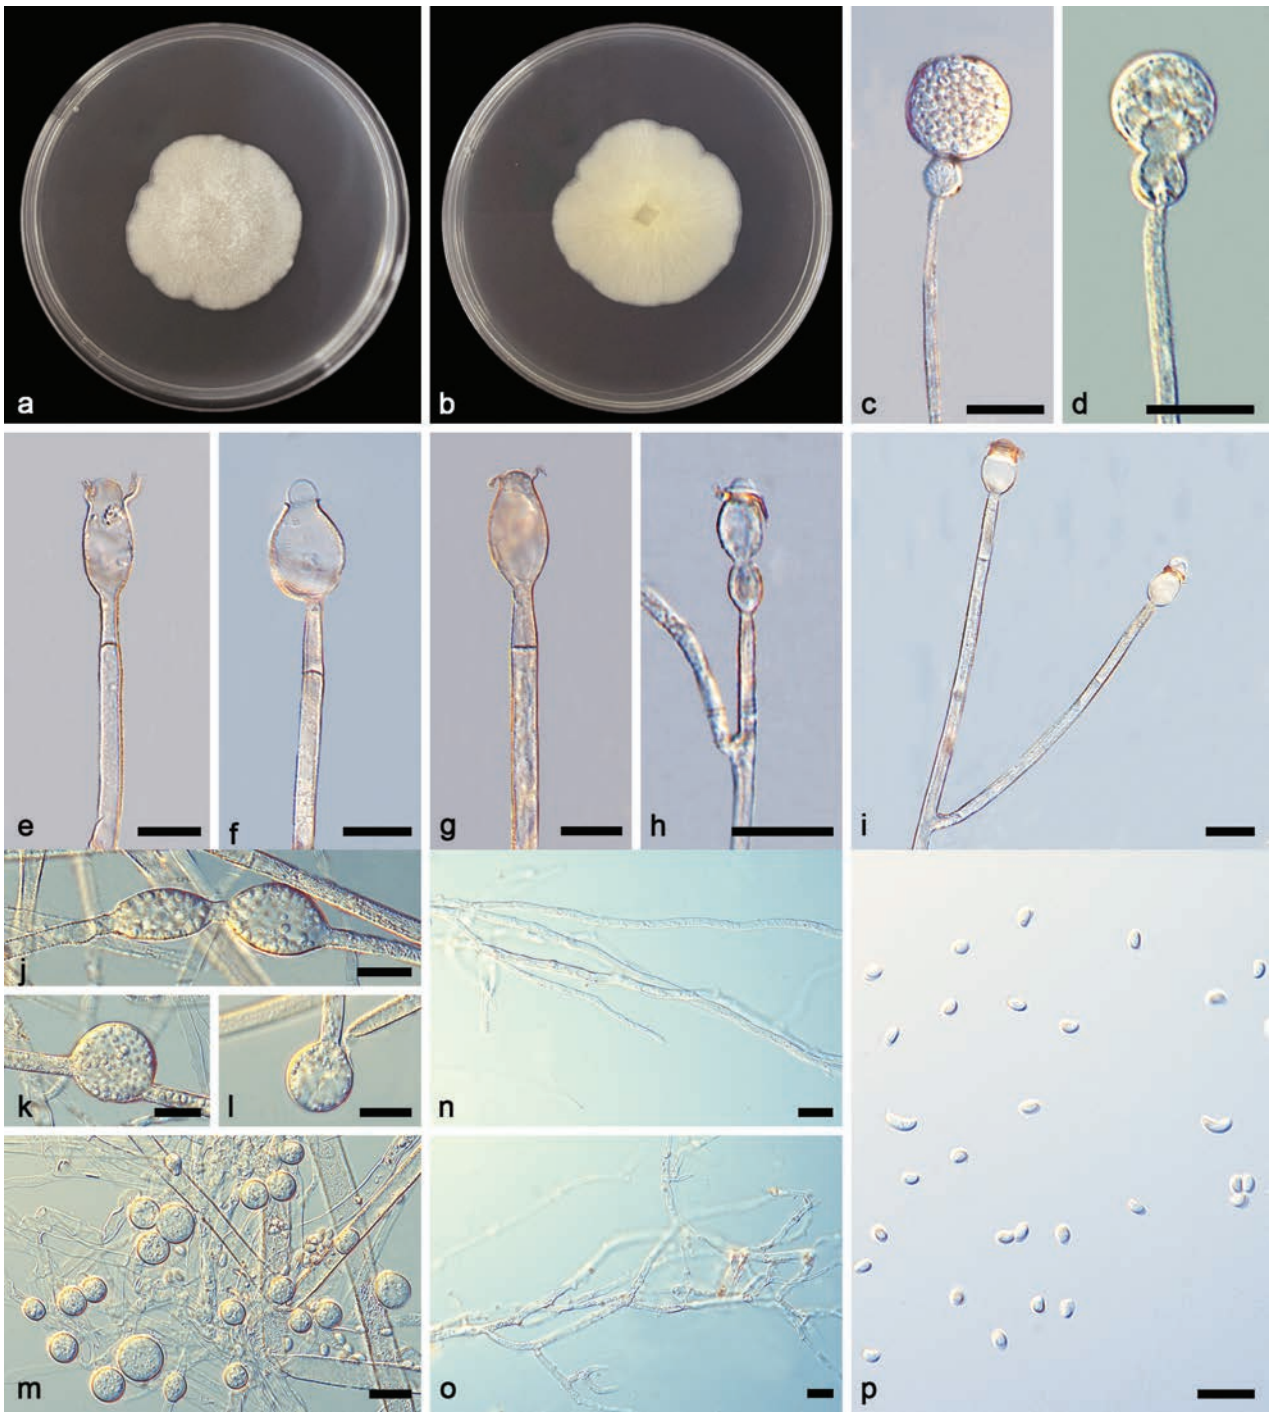

Figure 3. *Gongronella apophysata* ex-holotype CGMCC 3.27031 **a**, **b** colonies on PDA (**a** obverse **b** reverse) **c** an unbranched sporangiophore with a fertile sporangium **d** an unbranched sporangiophore with an immature sporangium **e–g** columellae, collars, apophyses and septa **h** branched sporangiophores with columellae, collars and apophyses **i** branched sporangiophores with columellae, collars and apophyses **j–l** chlamydospores **m** giant cells **n**, **o** rhizoids **p** sporangiospores. Scale bars: 10 μm (**c–p**).

Notes. Based on phylogenetic analyses of ITS+LSU+TEF+ACT+RPB1 sequences, the two isolates of the new species *Gongronella apophysata* form an independent clade with high support (MLBV = 98; Fig. 1), which is closely related to *G. zunyiensis*. In ITS, *G. apophysata* differs from the type species of *G. zunyiensis* by 13 base pairs. This new species differs morphologically

from *G. zunyiensis* in sporangium, columellae, apophyses and chlamydospore (Dong et al. 2019). *G. apophysata* has larger sporangia than *G. zunyiensis* (12.5–40.5 µm vs. 11.0–19.5 µm). *G. apophysata* differs from *G. zunyiensis* in the shape of columellae, the former being elliptic and the latter being hemispherical and globose. As for apophyses, *G. apophysata* and *G. zunyiensis* are remarkably different in shape and size, the former variously shaped, mostly ellipsoidal to olivary, 2.3–17.3 × 2.4–10.0 µm, partially subglobose, 4.6–10.2 × 4.3–10.0 µm, occasionally gourd-shaped, 11.4 × 4.9 µm and the latter hemispherical, 1.5–3.5 × 1.0–3.0 µm. *G. apophysata* is remarkably different from *G. zunyiensis* in shape and size of chlamydospores, the former being not uniform, mostly gourd-shaped, 23.5–35.4 × 10.8–14.0 µm, partially ellipsoidal, 18.6–21.4 × 10.3–18.5 µm and the latter being terminal or lateral, globose or subglobose, 7.0–10.5 µm in diameter. Combining morphological and molecular phylogenetic analyses, we classified the two isolates together as a new species *G. apophysata* allied to *G. zunyiensis*.

Gongronella bawanglingensis **Yi Xin Wang, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571903
Fig. 4

Etymology. The epithet "*bawanglingensis*" (Latin) refers to the location where the type was collected, Bawangling National Forest Park.

Type. China • Hainan Province, Changjiang Li Autonomous County, Bawangling National Forest Park (19.08593°N, 109.12275°E), from soil sample, 14 October 2023, Yi-Xin Wang (holotype HMAS 352730, ex-holotype strain CGMCC 3.27033).

Description. Colonies growing slowly on PDA in darkness at 25 °C, reaching 45.6–48.8 mm in diameter in seven days, white, cottony in the centre, on the reverse milky white. Rhizoids hyaline, branched, irregularly shaped. Stolons absent. Sporangiophores on aerial mycelia, erect or slightly curved, unbranched or slightly branched (up to 3 times), sympodially branched, 1.3–4.5 µm in width, hyaline, smooth, mostly aseptate or one-septate, no more than four-septate. Sterile (aborted) sporangia mainly on the top of short lateral branches of sporangiophores, mostly gourd-shaped. Fertile sporangia hyaline or light yellow, spherical, 4.2–18.5 µm in diameter, smooth and deliquescent-walled, leaving a collar after releasing sporangiospores. Columellae mostly hemispherical, 1.6–5.1 × 2.1–7.2 µm, sometimes arch-shaped, 1.4–3.7 × 2.6–8.8 µm, occasionally spherical, 2.3–6.1 × 2.5–8.1 µm, hyaline, smooth. Collars mostly distinct, 0.7–5.9 µm. Apophyses hyaline, smooth, variously shaped, mostly oval, 3.9–20.6 × 3.3–12.9 µm, sometimes subglobose, 4.8–12.2 × 4.7–12.3 µm, occasionally gourd-shaped. Sporangiospores not uniform, hyaline, smooth, mostly ovoid, 2.5–3.6 × 1.7–2.6 µm, partially reniform, 2.6–3.3 × 1.9–2.2 µm. Chlamydospores not uniform, gourd-shaped, 15.1–24.6 × 7.4–12.9 µm, ellipsoidal, 15.1–18.6 × 8.3–14.0 µm, suborbicular, 12.6–13.5 µm in diameter. Giant cells intercalary, globular, 3.2–6.9 µm in diameter. Zygospores not found.

Additional specimen examined. China • Hainan Province, Changjiang Li Autonomous County, Bawangling National Forest Park (19.08593°N, 109.12275°E), from soil sample, 14 October 2023, Yi-Xin Wang (living culture SAUCC 6946-1).

Figure 4. *Gongronella bawanglingensis* ex-holotype CGMCC 3.27033 **a**, **b** colonies on PDA (**a** obverse **b** reverse) **c**, **d** an unbranched sporangiophore with a fertile sporangium **e** branched sporangiophores with sterile (aborted) sporangia **f** branched sporangiophores with immature sporangia **g–i** columellae, collars, apophyses and septa **j**, **k** branched sporangiophores with columellae, collars and apophyses **l**, **m** chlamydospores **n** giant cells **o** rhizoids **p** sporangiospores. Scale bars: 10 μm (**c–p**).

GenBank accession numbers. CGMCC 3.27033 (ITS, PP195857; LSU, PP195958; TEF, PP50103; ACT, PP933951; RPB1, PP883965), and SAUCC 6946-1 (ITS, PP1195858; LSU, PP195959; TEF, PP850104; ACT, PP933952; RPB1, PP883964).

Notes. Based on phylogenetic analyses of ITS+LSU+TEF+ACT+RPB1 sequences, the two isolates of the new species *Gongronella bawanglingensis* form an independent clade with full support (MLBV = 100, BIPP = 1; Fig. 1), which is closely

related to *G. inconstans* and *G. qichaensis*. In ITS, *G. bawanglingensis* differs from *G. inconstans* by 21 base pairs. This new species differs morphologically from *G. inconstans* in columella, apophysis, colour and sporangiospore. *G. bawanglingensis* and *G. inconstans* are similar in the dominant shape of columellae, but the former is longer than that of the latter (2.1–7.2 µm vs. 2.0–3.9 µm). As for apophyses, *G. bawanglingensis* and *G. inconstans* are remarkably different from each other in shape and size, the former mostly oval, 3.9–20.6 × 3.3–12.9 µm, sometimes subglobose, 4.8–12.2 × 4.7–12.3 µm, occasionally gourd-shaped, the latter mostly long fusiform, 7.6–17.4 × 5.4–4.7 µm, sometimes oval, 5.5–8.8 × 4.4–6.3 µm, rarely egg-shaped, 5.0–6.4 × 4.2–5.7 µm. As for collars, the *G. inconstans* are more distinct than *G. bawanglingensis* (2.0–17.0 µm vs. 0.7–5.9 µm). As for sporangiospores, *G. bawanglingensis* and *G. inconstans* are similar in dominant shape, but the former is smaller in size than the latter (ovoid, 2.5–3.6 × 1.7–2.6 µm vs. 2.7–4.9 × 1.8–3.5 µm, reniform, 2.6–3.3 × 1.9–2.2 µm vs. 3.1–4.1 × 2.0–4.5 µm). Additionally, the *G. inconstans* has more shapes, except ovoid and reniform. In ITS, *G. bawanglingensis* differs from *G. qichaensis* by 28 base pairs. This new species differs morphologically from *G. qichaensis* in sporangium, columellae and apophysis (Wang et al. 2023a). The *G. bawanglingensis* has evidently smaller sporangia than *G. qichaensis*, 4.2–18.5 µm vs. 7.9–36.7 µm. In columella and apophysis, the two species have evident differences in shape. Combining morphological and molecular phylogenetic analyses, we classified the two isolates together as a new species *G. bawanglingensis* allied to *G. inconstans* and *G. qichaensis*.

Gongronella inconstans **Yi Xin Wang, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571905
Fig. 5

Etymology. The epithet "*inconstans*" (Latin) refers to the inconstant shape of apophyses.

Type. China • Hainan Province, Lingshui Li Autonomous County (18.69850°N, 109.88098°E), from soil sample, 7 Apr 72023, Yi-Xin Wang (holotype HMAS 352731, ex-holotype strain CGMCC 3.27029).

Description. Colonies growing slowly on PDA in darkness at 25 °C, reaching 31.2–36.8 mm in diameter in seven days, white, regular at edge and cottony, reversely milky white. Rhizoids hyaline, branched, irregular, ubiquitous. Stolons absent. Sporangiophores on aerial mycelia, erect or slightly curved, unbranched or slightly branched (2–3 times), 1.7–3.9 µm width, hyaline, smooth, mostly aseptate. Fertile sporangia hyaline or light yellow, spherical, 8.8–21.4 µm in diameter, smooth and deliquescent-walled, leaving a collar after releasing sporangiospores. Columellae mostly hemispherical, 1.2–2.4 × 2.0–3.9 µm, sometimes spherical, 3.2–7.2 × 3.4–7.2 µm, hyaline, smooth. Collars distinct, 2.0–17.0 µm wide. Apophyses hyaline, smooth, variously shaped, mostly long fusiform, 7.6–17.4 × 4.7–5.4 µm, sometimes oval, 5.5–8.8 × 4.4–6.3 µm, rarely egg-shaped, 5.0–6.4 × 4.2–5.7 µm. Sporangiospores not uniform, hyaline, smooth, mostly ovoid, 2.7–4.9 × 1.8–3.5 µm, sometimes reniform, 3.1–4.1 × 2.0–4.5 µm or subglobose, 2.4–4.1 µm in diameter, occasionally irregular, 5.0–8.0 × 2.5–3.2 µm. Chlamydospores present, gourd-shaped and irregular. Giant cells intercalary, globular, 4.2–8.0 µm in diameter. Zygospores not found.

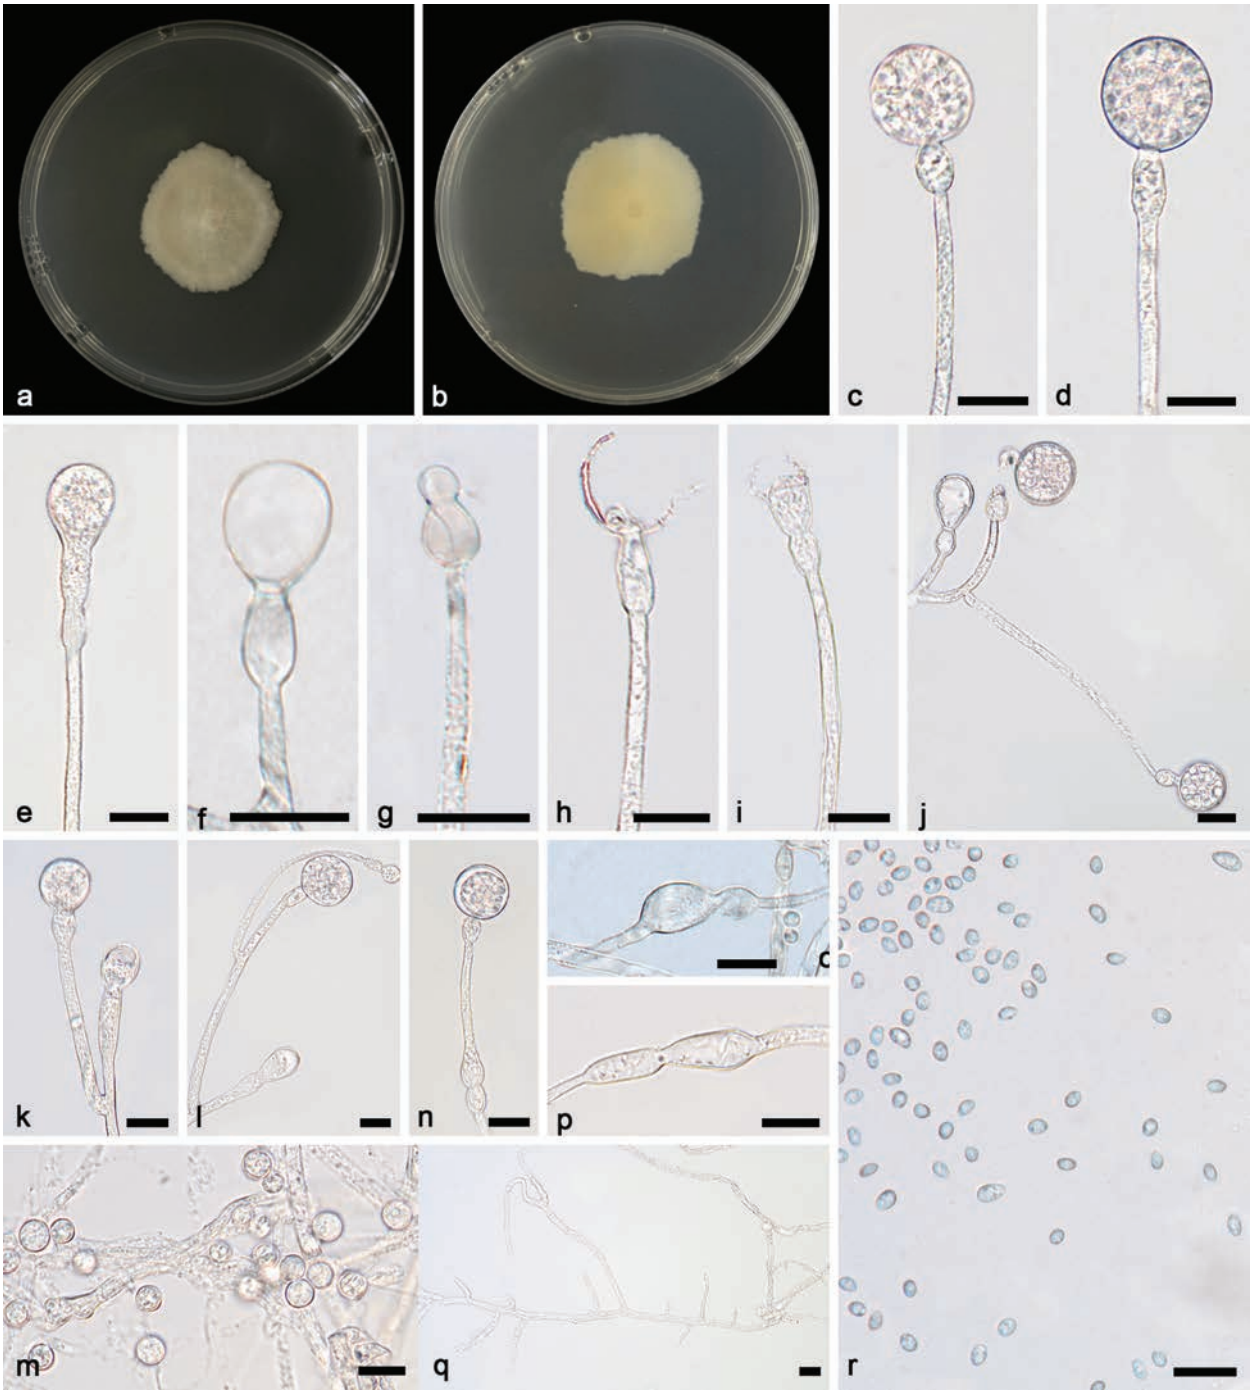

Figure 5. *Gongronella inconstans* ex-holotype CGMCC 3.27029 **a**, **b** colonies on PDA (**a** obverse **b** reverse) **c**, **d** an unbranched sporangiophore with a fertile sporangium **e** an unbranched sporangiophore with a premature sporangium **f** branched sporangiophores with aborted sporangia **g–i** columellae, collars, apophyses **j–l** branched sporangiophores with fertile sporangia, columellae, collars and apophyses **n** fertile sporangium with protuberance **o, p** chlamydospores **m** giant cells **q** rhizoids **r** sporangiospores. Scale bars: 10 μm (**c–r**).

Additional specimen examined. China • Hainan Province, Lingshui Li Autonomous County (18.69850°N, 109.88098°E), from soil sample, 7 April 2023, Yi-Xin Wang (living culture SAUCC 4113-1).

GenBank accession numbers. CGMCC 3.27029 (ITS, PP1955849; LSU, PP195950; TEF, PP850091; ACT, PP933941; RPB1, PP842874), and SAUCC 4113-1 (ITS, PP105850; LSU, PP195951; TEF, PP850092, ACT, PP933942; RPB1, PP842873).

Note. Based on phylogenetic analyses of ITS+LSU+TEF+ACT+RPB1 sequences, the two isolates of the new species *Gongronella inconstans* form an independent clade with full support (MLBV = 100, BIPP = 1; Fig. 1), which is closely related to *G. qichaensis* with high support (BIPP = 0.96; Fig. 1). In ITS, *G. inconstans* differs from *G. qichaensis* by 28 base pairs. This new species differs morphologically from *G. inconstans* in sporangium, columellae and apophysis. As for sporangium, the *G. inconstans* is smaller than the *G. qichaensis*, 8.8–21.4 µm vs. 7.9–36.7 µm. The *G. inconstans* and *G. qichaensis* are different in size and shape of columellae (Wang et al. 2023a). The *G. inconstans* mostly hemispherical, 1.2–2.4 × 2.0–3.9 µm, sometimes spherical, 3.2–7.2 × 3.4–7.2 µm. Additionally, the columellae of *G. qichaensis* is mostly ellipsoidal, 0.8–6.5 × 1.2–8.1 µm, sometimes sub-hemispherical to curved, 1.0–2.0 × 2.5–4.5 µm. *G. inconstans* and *G. qichaensis* are evidently different in apophysis shape. The former mostly long fusiform, sometimes oval-shaped and rarely egg shaped. The latter mostly pear-shaped to oval, partially elliptical or sub-globose. Combining morphological and molecular phylogenetic analyses, we classified the two isolates together as a new species: *G. inconstans* allied to *G. qichaensis*.

***Gongronella pamphilae* Y.P. Tan, Bishop-Hurley & R.G. Shivas**
Fungal Names: FN 900776
Fig. 6

Etymology. Named after Pamphilae of Epidaurus (ca. 1st century AD), a historian of Egyptian descent who lived in Greece.

Description. Colonies growing slowly on PDA in darkness at 25 °C, reaching 36.6–44.6 mm in diameter in seven days, white, regular at edge and cottony in the centre, reversely milky white. Rhizoids hyaline, branched, irregular. Stolons absent. Sporangiophores on aerial mycelia, erect or slightly curved, unbranched or slightly branched (1–2 times), 3.7–154.9 × 1.4–4.1 µm, hyaline, smooth, mostly aseptate, no more than two-septate. Fertile sporangia hyaline or light yellow, spherical, 13.8–30.8 µm in diameter, smooth and deliquescent-walled, leaving a collar after releasing sporangiospores. Columellae mostly hemispherical, 1.8–4.7 × 2.0–7.7 µm, sometimes arc-shaped, 0.5–1.6 × 3.3–4.6 µm, occasionally subglobose, 4.8–6.4 × 5.9–6.9 µm, hyaline, smooth. Collars distinct, 1.0–5.1 µm wide. Apophyses hyaline, smooth, variously shaped, mostly subglobose, 5.7–8.1 × 5.6–9.0 µm, sometimes ellipsoidal, 4.8–6.9 × 4.8–6.1 µm. Sporangiospores not uniform, hyaline, smooth, reniform, 3.0–5.5 × 1.8–3.4 µm, ovoid, 2.5–5.6 × 1.8–3.7 µm. Chlamydospores present, ellipsoidal. Giant cells intercalary, globose, 4.0–8.1 µm in diameter. Zygospores not found.

Additional specimen examined. China • Hainan Province, Lingshui Li Autonomous County, Shizhi Village Road (18.70178°N, 109.83679°E), from soil sample, 10 April 2023, Yi-Xin Wang (specimen HMAS 352732, living culture CGMCC 3.27027, SAUCC 4031-2).

GenBank accession numbers. CGMCC 3.27027 (ITS, PP195845; LSU, PP195946; TEF, PP850086; ACT, PP933935; RPB1, PP850081), and SAUCC 4031-2 (ITS, PP195846; LSU, PP195947; TEF, PP850085; ACT, PP933936; RPB1, PP850082).

Note. Based on phylogenetic analyses of ITS+LSU+TEF+ACT+RPB1 DNA sequences, the two isolates of the new record species *Gongronella pamphilae* form

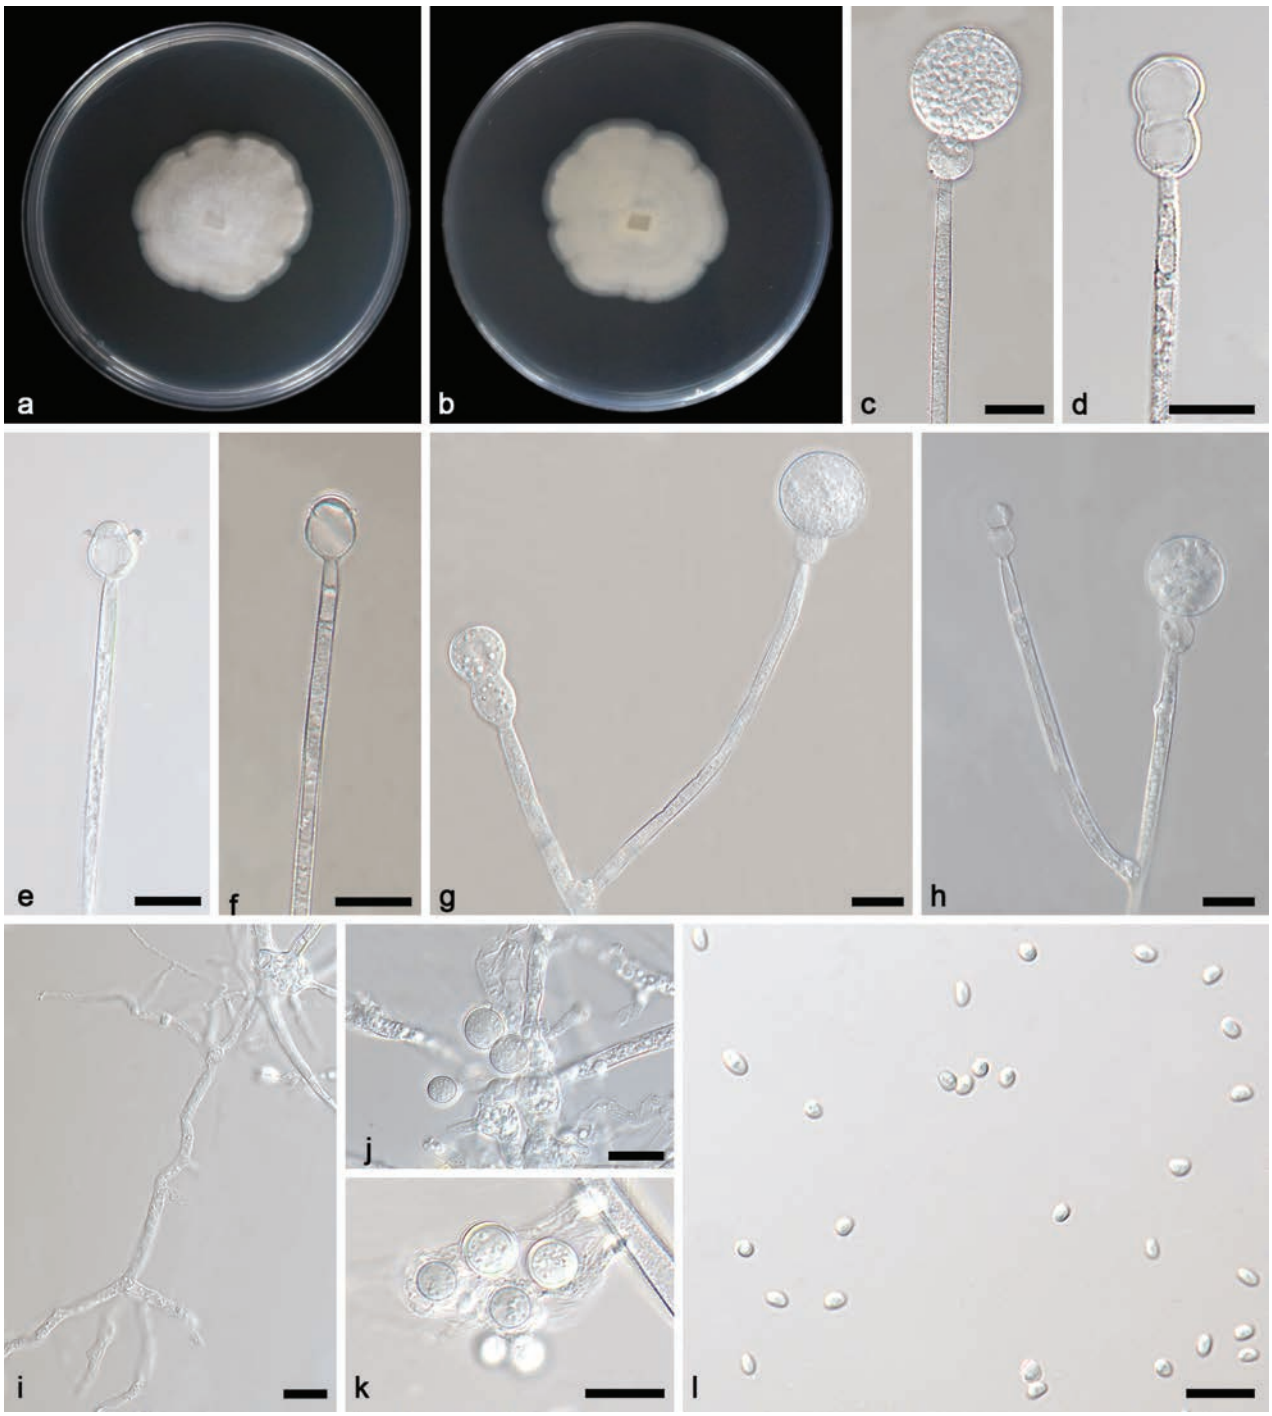

Figure 6. *Gongronella pamphilae* ex-living culture CGMCC 3.27027 **a**, **b** colonies on PDA (**a** obverse **b** reverse) **c** an unbranched sporangiophore with a fertile sporangium **d** an unbranched sporangiophore with an aborted sporangium **e, f** an unbranched sporangiophore with columellae, apophyses and collars **g, h** branched sporangiophores with columellae, collars, apophyses **i** Rhizoids **j, k** giant cells **l** sporangiospores. Scale bars: 10 µm (**c–l**).

an independent clade with full support (MLBV = 100; Fig. 1), which is closely related to *G. pamphilae* (MLBV = 100; BI = 1, Fig. 1). In ITS, the two isolates differ from *G. pamphilae* by only 2 base pairs. As no morphological descriptions were provided for the *G. pamphilae* in its protologue, we classified the two isolates together as members of *G. pamphilae* just based on molecular phylogenetic analyses. Consequently, we provide herein a supplemental description for the species.

***Gongronella pingtangensis* Yi Xin Wang, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571904
Fig. 7

Etymology. The epithet "*pingtangensis*" (Latin) refers to the location where the type was collected, Pingtang County.

Type. China • Qiannan Buyi and Miao Autonomous Prefecture, Pingtang County, Kapu Maonan Town (25.79510°N, 107.38631°E), from soil sample, 7 August 7 2023, Yi-Xin Wang (holotype HMAS 352732, ex-holotype strain CGMCC 3.27032).

Description. Colonies growing slowly on PDA in darkness at 25 °C, reaching 38.8–45.6 mm in diameter in seven days, white, cottony, in reverse milky white. Rhizoids hyaline, branched, irregular. Stolons absent. Sporangiophores on aerial mycelia, erect or slightly curved, unbranched, or slightly branched (1–4 times), sympodially branched, 1.4–5.9 µm in width, hyaline, smooth, mostly aseptate or one-septate. Sterile (aborted) sporangia predominantly on the top of short lateral branches of sporangiophores. Fertile sporangia hyaline or light yellow, spherical, 14.2–27.1 µm in diameter, smooth and deliquescent-walled, leaving a collar after releasing sporangiospores. Columellae mostly hemispherical, 2.3–4.0 × 2.8–6.9 µm, partially arch-shaped, 0.9–1.5 × 4.1–4.9 µm, rarely spherical, 4.4–6.0 × 5.1–6.9 µm, hyaline, smooth. Collars mostly distinct, 0.6–8.7 µm wide. Apophyses hyaline, smooth, variously shaped, mostly oval, 7.1–19.8 × 6.9–15.9 µm, partially bowling pin-shaped, 15.6–17.5 × 8.5–9.4 µm, rarely egg-shaped, 4.6–9.8 × 3.6–8.7 µm. Sporangiospores not uniform, hyaline, smooth, mostly ovoid, 2.8–3.9 × 2.0–2.5 µm, sometimes reniform, 2.9–3.6 × 1.9–2.4 µm and globose, 2.1–2.7 µm in diameter, occasionally irregular, 4.8–6.2 × 2.1–2.8 µm. Chlamydospores absent. Giant cells in rhizoids, intercalary, globose, 5.2–6.8 µm in diameter. Zygospores not found.

Additional specimen examined. China • Qiannan Buyi and Miao Autonomous Prefecture, Pingtang County, Kapu Maonan Town (25.79510°N, 107.38631°E), from soil sample, 7 August 2023, Yi-Xin Wang (living culture SAUCC 5676-2).

GenBank accession numbers. CGMCC 3.27032 (ITS, PP195855; LSU, PP195956; TEF, PP850101; ACT, PP933949; RPB1, PP842880), and SAUCC 5676-4 (ITS, PP195856; LSU, PP195957; TEF, PP850102; ACT, PP933950; RPB1, PP842879).

Note. Based on phylogenetic analyses of ITS+LSU+TEF+ACT+RPB1 sequences, the two isolates of the new species *G. pingtangensis* form an independent clade with high support (MLBV = 100, BIPP = 0.84; Fig. 1), which is closely related to *G. namwonensis* with high support (BIPP = 1; Fig. 1). In ITS, *G. pingtangensis* differs from *G. namwonensis* by 14 base pairs. This new species differs morphologically from *G. namwonensis* in columellae, apophysis and giant cell (Crous et al. 2020). *G. pingtangensis* and *G. namwonensis* greatly differ from each other in shape of columellae, the former being mostly hemispherical, partially arch-shaped, rarely spherical and the latter being globose, subglobose, hemispherical, nipple-like and ellipsoidal. As for apophyses, *G. pingtangensis* and *G. namwonensis* obviously differ from each other in shape, the former being mostly oval, partially bowling pin-shaped, rarely egg-shape and the latter being subglobose and ellipsoid, sometimes with a truncated base. As for giant cells, the *G. namwonensis* varies in shape more than *G. pingtangensis*. Combining morphological and molecular phylogenetic analyses, we classified the two isolates together as a new species *G. pingtangensis* allied to *G. namwonensis*.

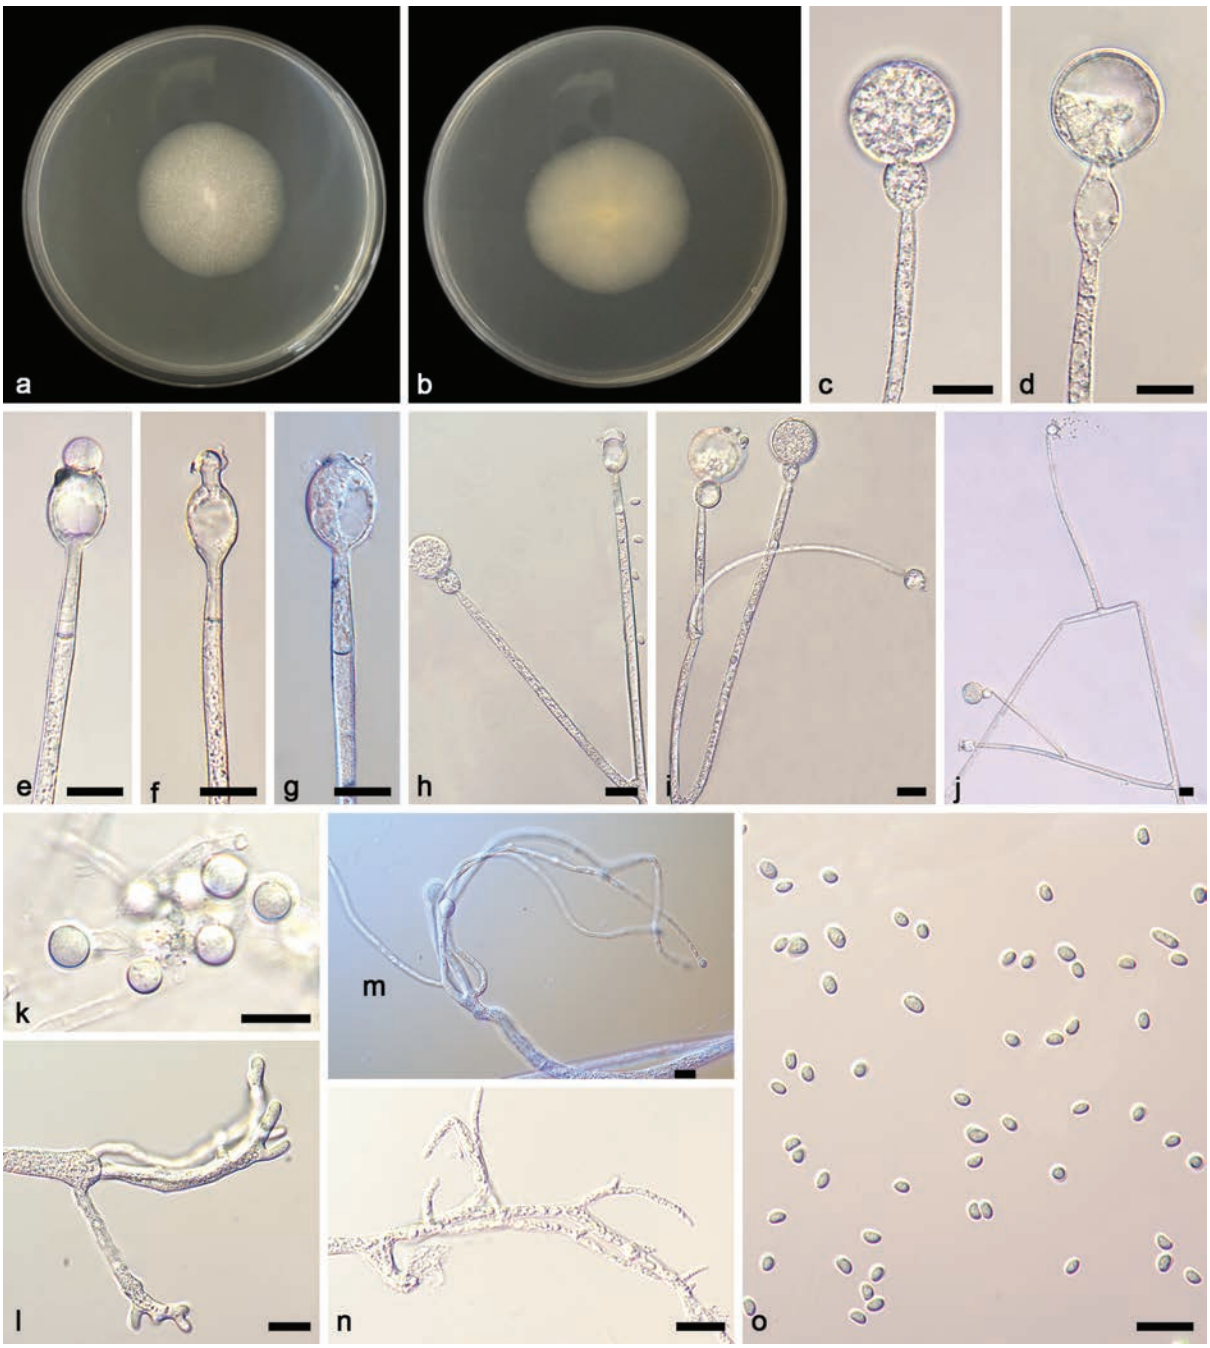

Figure 7. *Gongronella pingtangensis* ex-holotype CGMCC 3.27032 **a**, **b** colonies on PDA (**a** obverse **b** reverse) **c**, **d** an unbranched sporangiophore with a fertile sporangium **e–g** columellae, collars, apophyses and septa **h–j** branched sporangiophores with fertile sporangia, columellae, collars, apophyses and septa **k** giant cells **i–n** rhizoids **o** sporangiospores. Scale bars: 10 μm (**c–o**).

Gongronella reniformis **Yi Xin Wang, H. Zhao & X.Y. Liu, sp. nov.**
Fungal Names: FN 571630
Fig. 8

Etymology. The epithet "*reniformis* " (Latin) refers to the reniform sporangiospores.

Type. China • Hainan Province, Changjiang Li Autonomous County, Qicha Town (19.11750°N, 109.15000°E), from soil sample, 11 April 2023, Yi-Xin Wang (holotype HMAS 352727, ex-holotype strain CGMCC 3.27030).

Description. Colonies on PDA in darkness at 25 °C growing slowly, reaching 39.4–41.8 mm in diameter in seven days, white, regular at edge and cottony in the centre, on reverse milky white. Rhizoids hyaline, branched, irregular, sometimes with giant cells in the terminal. Stolons absent. Sporangiophores on aerial mycelia, erect or slightly curved, unbranched or slightly branched (1–3 times), 3.4–157.9 × 0.8–3.4 µm, hyaline, smooth, mostly aseptate, partially no more than two-septate. Sterile (aborted) sporangia predominantly on the top of short lateral branches of sporangiophores, gourd-shaped, 15.0–19.9 × 3.1–10.9 µm. Fertile sporangia hyaline or light yellow, spherical, 7.9–26.0 µm in diameter, smooth and deliquescent-walled, leaving a collar after releasing sporangiospores. Columellae mostly elliptic, 1.7–4.6 × 1.4–5.2 µm, sometimes sub-hemispherical, 1.4–2.6 × 3.3–4.9 µm, hyaline, smooth. Collars distinct, 2.1–4.3 µm. Apophyses hyaline, smooth, variously shaped, pear-shaped, 3.3–8.5 × 3.0–7.3 µm, ellipsoidal, 4.6–10.1 × 2.9–7.8 µm. Sporangiospores not uniform, hyaline, smooth, mostly reniform, 2.8–3.5 × 1.8–2.3 µm, occasionally ovoid, 3.1–3.4 × 1.7–2.0 µm. Chlamydospores, mostly ellipsoidal, 7.3–12.5 × 6.1–11.2 µm, sometimes irregular. Giant cells intercalary, globose, 3.5–10.0 µm in diameter. Zygospores not found.

Additional specimen examined. China • Hainan Province, Changjiang Li Autonomous County, Qicha Town (19.11750°N, 109.15000°E), from soil sample, 11 April 2023, Yi-Xin Wang (living culture SAUCC 4142-5).

GenBank accession numbers. CGMCC 3.27030 (ITS, PP195851; LSU, PP195952; TEF, PP850095; ACT, PP933943; RPB1, PP84875), SAUCC 4142-5 (ITS, PP195852; LSU, PP195953; TEF, PP850096; ACT, PP933944; RPB1, PP842876).

Notes. Based on phylogenetic analyses of ITS+LSU+TEF+ACT+RPB1 sequences, the two isolates of the new species *Gongronella reniformis* form an independent clade with full support (MLBV = 100, BIPP = 1; Fig. 1), which is close to *G. pamphilae* and *G. brasiliensis* with a high support (MLBV = 89, BIPP = 1; Fig. 1). Comparing ITS sequences showed that *G. reniformis* is relatively closely related to *G. pamphilae* (44 bp of dissimilarity) and *G. brasiliensis* (40 bp of dissimilarity). There were no morphological descriptions of *G. pamphilae* in its protologue, so the morphological comparison was made between *G. reniformis* and the *G. pamphilae* strains identified in this study. This new species differs morphologically from *G. pamphilae* in sporangium, columellae, apophysis, sporangiospore. The sporangium of *G. reniformis* is smaller than that of *G. pamphilae* (7.9–26.0 µm vs. 13.8–30.8 µm). *G. reniformis* and *G. pamphilae* are different from each other mainly in shape and size of columellae, the former being mostly elliptic, 1.7–4.6 × 1.4–5.2 µm, sometimes sub-hemispherical, 1.4–2.6 × 3.3–4.9 µm and the latter being mostly hemispherical, 1.8–4.7 × 2.0–7.7 µm, sometimes arc-shaped, 0.5–1.6 × 3.3–4.6 µm. The *G. reniformis* and *G. pamphilae* are different from each other in dominant shape and size of apophyses, the former being pear-shaped, 3.3–8.5 × 3.0–7.3 µm and ellipsoidal, 4.6–10.1 × 2.9–7.8 µm, the latter being spherical, 5.7–8.1 × 5.6–9.0 µm and ellipsoidal, 4.8–6.9 × 4.8–6.1 µm. The sporangiospores of *G. reniformis* are smaller than those of *G. pamphilae* (reniform, 2.8–3.5 × 1.8–2.3 µm vs. 3.0–5.5 × 1.8–3.4 µm, ovoid, 3.1–3.4 × 1.7–2.0 µm vs. 2.5–5.6 × 1.8–3.7 µm). This new species differs morphologically from *G. brasiliensis* in sporangiophore, columellae and giant cells (Tibpromma et al. 2017). In sporangiophores, the *G. renformis* differs from the *G. brasiliensis* in size, 3.4–157.9 × 0.8–3.4 µm vs. 26.5–320.0 × 2.5–5.0 µm. As for columellae,

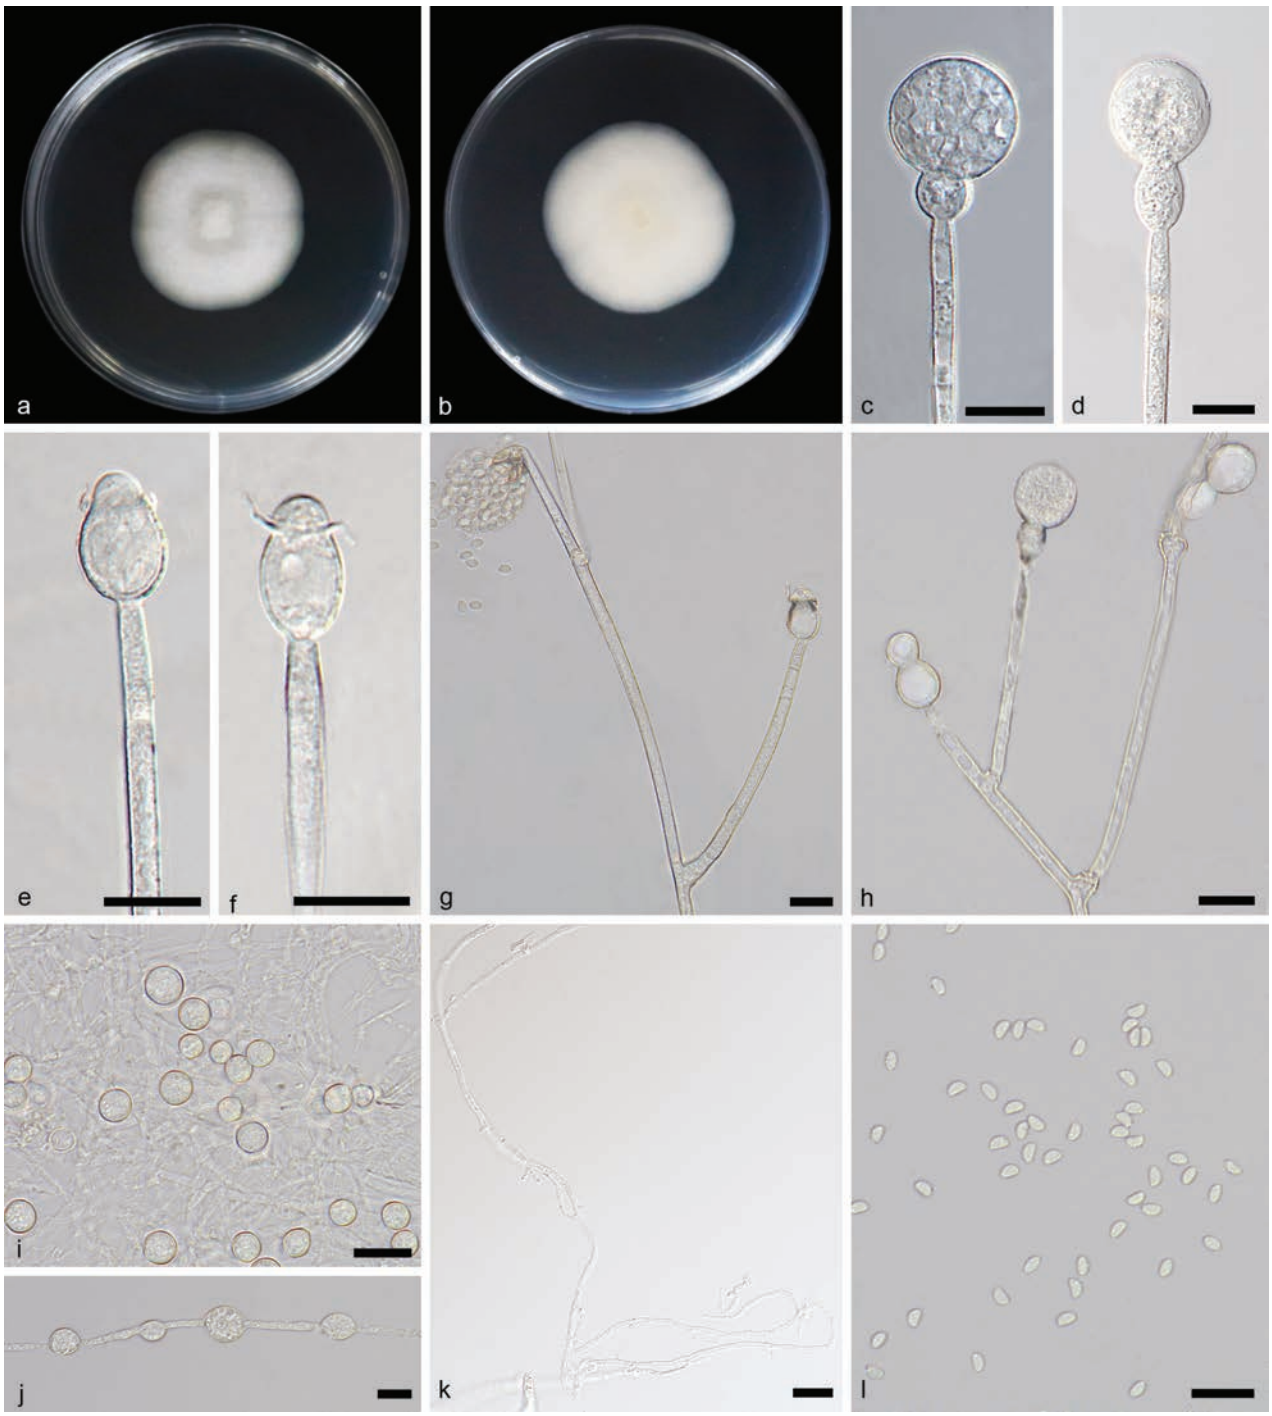

Figure 8. *Gongronella reniformis* ex-holotype CGMCC 3.27030 **a**, **b** colonies on PDA (**a** obverse **b** reverse) **c** an unbranched sporangiophore with a fertile sporangium **d** an unbranched sporangiophore with an immature sporangium **e**, **f** columellae, collars and apophyses **g** branched sporangiophores with shedding sporangia, columellae, collars, apophyses and septa **h** branched sporangiophores with fertile sporangia and sterile (aborted) sporangia **i** giant cells **j** chlamydospore **k** rhizoids **l** sporangiospores. Scale bars: 10 μm (**c–l**).

the *G. renformis* and *G. brasiliensis* are different in shape. The former mostly elliptic, sometimes sub-hemispherical. The latter globose, subglobose and conical-cylindrical. The *G. renformis* is evidently smaller than *G. brasiliensis* in giant cells, 3.5–10.0 μm vs. up to 48 μm. Combining morphological and molecular phylogenetic analyses, we classified the two isolates as a new species *G. reniformis*.

Morphological comparisons and key to the species of *Gongronella*

Together with the six new species proposed in this study, a total of 25 species of *Gongronella* have been described worldwide. Except *G. banzhaoae*, morphological comparisons were made amongst 18 species published before and six species newly proposed in this study (Table 4). We provide herein a synoptic key for these species. Characteristics adopted in the key include colonies, sporangiophores, sporangia, columellae, apophyses, sporangiospores and giant cells.

1 Giant cells known **2**
– Giant cells unknown **15**
2 Aborted sporangia known **3**
– Aborted sporangia unknown ..... ***G. hydei***
3 Fertile sporangia > 25 µm diameter **4**
– Fertile sporangia < 25 µm diameter **10**
4 Sporangiospores mainly not reniform **5**
– Sporangiospores mainly reniform **7**
5 Columellae mainly ellipsoidal ..... ***G. qichaensis***
– Columellae mainly not ellipsoidal **6**
6 Fertile sporangia 14.2–27.1 µm ..... ***G. pingtangensis***
– Fertile sporangia, 13.0–41.0 µm ..... ***G. lacrispora***
7 Sporangiospores > 4 µm wide **8**
– Sporangiospores < 4 µm wide **10**
8 Sporangiophores branched ≥ 3 times ..... ***G. namwonensis***
– Sporangiophores branched < 3 times **9**
9 Columellae mainly globose and subglobose, 4.0–8.0 µm ..... ***G. brasiliensis***
– Columellae mainly hemispherical, 1.8–4.7 × 2.0–7.7 µm ..... ***G. pamphilae***
10 Apophyses mainly reniform, 2.8–3.5 × 1.8–2.3 µm ..... ***G. reniformis***
– Apophyses mainly reniform, 3.2–5.5 × 1.7–3.1 µm ..... ***G. apophysata***
11 Sporangiophores branched > 3 times **12**
– Sporangiophores branched ≤ 3 times **14**
12 Giant cells > 6 µm diameter **13**
– Giant cells < 6 µm diameter ..... ***G. abortosporangia***
13 Columellae mainly subspherical and ovoid, 2.6–5.2 × 3.2–6.5 µm ..... ***G. oleae***
– Columellae mainly hemispherical, 4.4–5.6 × 8.5–9.0 µm ..... ***G. multiramosa***
14 Apophyses oval, subglobose and gourd-shaped ..... ***G. bawanglingensis***
– Apophyses long fusiform, oval and egg-shaped ..... ***G. inconstans***
15 Fertile sporangia > 25 µm diameter **16**
– Fertile sporangia < 25 µm diameter **17**
16 Apophyses vasiform, 5.0–15.0 × 4.5–15.0 µm ..... ***G. pedratalhadensis***
– Apophyses ellipsoidal to subglobose, 4.5–8.5 × 4.5–6.0 µm ..... ***G. sichuanensis***
17 Columellae hemispherical **18**
– Columellae not hemispherical **19**
18 Apophyses urn-shaped to subglobose, 6.0–12.0 × 6.0–10.0 µm ..... ***G. chlamydospora***
– Apophyses oval, 7.0–10 × 8.0–8.7 µm ..... ***G. butleri***
19 Sporangiospores ≥ 3.5 µm long **20**
– Sporangiospores < 3.5 µm long **21**

20 Apophyses globose to subglobose, 3.5–6.5 × 3.0–7.0 µm..... ***G. eborensis***
– Apophyses pyriform to subglobose, 8.0–12.0 × 7.0–9.5 µm... ***G. multispora***
21 Sporangiospores ≥ 4 µm width, mostly not bean-shaped **22**
– Sporangiospores < 4 µm width, mostly bean-shaped.....**23**
22 Columellae hemispherical, spherical or ovoid, 2.5–12.0 × 2.0–12.0 µm ....***G. guangdongensis***
– Columellae hemispherical and globose, 2.0–3.0 × 3.5–7.0 µm..... .....***G. zunyiensis***
23 Sporangiospores 2.0–3.5 × 2.0–2.5 µm.....***G. orasabula***
– Sporangiospores 1.7–2.1 × 2.1–3.8 µm.....***G. koreana***

Discussion

Southern China is located in tropical and subtropical areas, which belong to tropical monsoon climate and subtropical monsoon climate. All the samples used in this study were collected from these areas, including Hainan, Sichuan, Yunnan and Guizhou Provinces. This is consistent with the geographical distribution of the species of *Gongronella*, mainly inhabiting tropical and subtropical regions.

The genus *Gongronella* was established in 1952 and its type *Gongronella urceolifera* was synonymised with *Gongronella butleri* whose basionym is *Absidia butleri* (Ribaldi 1952). Numbers of this genus have increased rapidly recently, with as many as 17 species being described between 2015 and 2024 and the genus currently has a total of 25 members including the six new species proposed herein, all of which are listed in Table 3. However, there are no systematic analyses of the morphological characteristics of the species of *Gongronella*. In this study, the morphological characteristics of the 24 species of *Gongronella* were comparatively analysed (Table 4), except *G. banzhaoae*. Since *G. banzhaoae* only has molecular data and no morphological description, it is not compared in this study.

Since 2019, phylogenetic analyses of *Gongronella* have mainly been conducted on the basis of morphological characteristics and ITS+LSU sequence (Zhang et al. 2019). In this study, new TEF, ACT and RPB1 protein-coding sequences were added for the construction of phylogenetic trees and the results were basically consistent with previous studies based on ITS+LSU. Twelve strains were grouped into six individual clades and two strains were grouped along with *G. pamphilae*. Compared with *G. multiramosa*, *G. abortosporangia* has more abundant and various aborted sporangia, smaller fertile sporangia and smaller columellae (Wang et al. 2023a). Compared with *G. pamphilae*, *G. reniformis* has smaller sporangia and sporangiospores, as well as different shapes of columellae and apophyses. Compared with *G. brasiliensis*, *G. reniformis* has smaller sporangiophores, different columella shapes and smaller giant cells (Tibpromma et al. 2017). Compared with *G. zunyiensis*, *G. apophysata* has larger sporangia, as well as different shapes of columellae, apophyses and chlamydospores (Dong et al. 2019). Compared with *G. inconstans*, *G. bawanglingensis* has smaller sporangiospores, larger columellae, different shapes and sizes of apophyses. Compared with *G. qichaensis*, the *G. bawanglingensis* has smaller sporangia, different columellae and apophysis shapes (Wang et al. 2023a). *G. pingtangensis* and *G. namwonensis* are different in size and shape of columellae (hemispherical vs. globose) and apophyses (oval vs. subglobose). *G. namwonensis* has more shapes of giant cells (Crous et al. 2020).

Table 4. Morphological comparisons of *Gongronella* species.

Species	Colonies	Sporangiophores	Sporangia	Columellae	Apophyses	Sporangiospores	Giant cell	Reference
G. abortosporangia	PDA: dark 25 °C 7 d 24.6–26.2 mm diam., white, regular at edge and cottony in the centre, in reverse milky white	unbranched or branched 1–6 times, 4.0–96.8 × 1.0–4.2 µm, mostly aseptate, partially 1-septate, rarely 2-septate, occasionally containing a line of oil droplets	Aborted: mostly gourd-shape, 11.6–16.7 × 5.5–17.7 µm, partially elliptical with slight shrinkage, 12.5–18.0 × 6.7–10.6, occasionally clavate, 20.1–22.7 × 9.5–10.4 µm; Fertile: 7.0–23.2 µm diam	mostly hemispherical, 2.5–4.2 × 3.6–7.4 µm, sometimes sub-hemispherical, 1.3–3.9 × 3.6–5.5 µm	mostly cup-shaped, 1.9–8.6 × 2.1–6.7 µm, partially hemispherical, 2.7–5.5 × 2.8–7.4 µm, occasionally pear-shaped, 8.2 × 7.2 µm	ovoid, 2.6–3.5 × 1.7–2.1 µm, reniform, 2.9–3.5 × 1.7–2.3 µm	intercalary, globular, subglobular, 2.6–4.6 µm diam.	This study
G. apophysata	PDA: dark 25 °C 7 d 17.9–21.2 mm in diam., white, irregular at edge and cottony in centre, in reverse milky white	unbranched or branched 1–2 times, 11.2–190.9 × 1.6–3.9 µm, mostly aseptate or 1-septate, occasionally 2-septate	Aborted: gourd-shape, 14.0 × 8.3 µm; Fertile: spherical, 12.5–40.5 µm diam.	elliptic, 2.6–4.0 × 2.1–5.5 µm, sub-hemispherical, 1.4–2.7 × 2.2–4.3 µm	mostly ellipsoidal to olivary, 2.3–17.3 × 2.4–10.0 µm, partially subglobose, 4.6–10.2 × 4.3–10.0 µm, occasionally gourd-shaped, 11.4 × 4.9 µm	mostly reniform, 3.2–5.5 × 1.7–3.1 µm, ovoid, 2.5–3.7 × 1.7–2.6 µm, occasionally sub-orbicular, 1.7–2.5 µm	intercalary, globular, 4.4–10.5 µm diam.	This study
G. bawanglingensis	PDA: dark 25 °C 7 d 22.8–24.4 mm diam., white, cottony in centre, in reverse milky white	unbranched or sympodially branched 1–3 times, 1.3–4.5 µm wide, mostly aseptate or 1-septate, occasionally up to 4-septate	Aborted: mostly gourd-shaped; Fertile: spherical, 4.2–18.5 µm diam.	mostly hemispherical, 1.6–5.1 × 2.1–7.2 µm, some arch-shaped, 1.4–3.7 × 2.6–8.8 µm, spherical, 2.3–6.1 × 2.5–8.1 µm	oval-shaped, 3.9–20.6 × 3.3–12.9 µm, subglobose-shaped, 4.8–12.2 × 4.7–12.3 µm, occasionally gourd-shaped	mostly ovoid, 2.5–3.6 × 1.7–2.6 µm, reniform, 2.6–3.3 × 1.9–2.2 µm	intercalary, globular, 3.2–6.9 µm diam.	This study
G. brasiliensis	MEA: 25 °C 7 d 1.0–2.0 mm high 60.0 mm diam., white, cottony, irregular at edge, reverse cream to buff	26.5–320.0 × 2.5–5.0 µm, solitary, arising from stolons or in whorls of two, often with a single branch, 1- or 2-septate below apophyses	Aborted: globose, 5.0–17.0 µm diam.; Fertile: globose, subglobose, 9.5–30.0 µm diam.	globose, subglobose, (3.0–)4.0–8.0(–9.0) µm, conical-cylindrical, 1.5–2.5 × 2.0–3.0 µm, some very small, up to 1 µm diam.	globose, (3.0–)4.0–5.0(–6.0) µm diam., vase-shaped, (3.0–)4.0 × 12.0(–14.5) µm, ellipsoidal, 5.0–10.0(–12.0) × 3.0–7.0(–8.5) µm	reniform, 1.5–4.0 × 1.5–2.5 µm, ellipsoid to fusiform, 2.0–6.5 × 1.5–3.0 µm, ellipsoid with a flattened end, 2.5–7.5 × 1.5–4.0 µm	globose, subglobose, ovoid, some hypha-like, irregularly swollen, up to 48.0 µm diam.	Tibpromma et al. (2017)
G. butleri	White turf	simply or irregularly branched, 2.1–3.1 µm wide, always 1-septate	Fertile: globose, 16.5–22.7 µm		swollen, oval-shaped, 7.0–10 × 8.0–8.7 µm	oval to flattened on one side to reniform, 2.5–7.2 × 1.7–4.7 µm		Ribaldi (1952), Babu et al. (2015)
G. chlamydospora	PDA: 27 °C 11 d 90.0 mm diam., floccose, at first white, then drab grey	unbranched or simply branched, hyaline, slightly constricted at top	Fertile: globose, 8.5–17.0 µm diam.	ovoid to depressed subglobose, 3.0–5.5 × 3.5–6.5 µm	urn-shaped to subglobose, 6.0–12.0 × 6.0–10.0 µm	ellipsoid, reniform or irregular, 2.0–3.0 × 1.0–2.0 µm		Zhao et al. (2023)
G. eborensis	PDA: 25 °C 5 d 28.0–32.0 mm diam.	46.0–94.0 × 1.5–3.0 µm, irregularly or simply branched, always 1-septate under apophyses	Fertile: globose to subglobose, 7.5–16.0 × 7.0–13.0 µm	hemispherical to subglobose, 11.5–5.5 × 8.2–3.2 µm	globose to subglobose, 3.5–6.5 × 3.0–7.0 µm	reniform to fusiform-elliptical, 2.6–3.8 × 1.2–1.6 µm		Martins et al. (2020)
G. guangdongensis	PDA: 25 °C 13 d 1–2 mm high, 50.0 mm diam., white or pale, irregular at edge; in reverse buff to honey	irregularly or simply branched, 28.0–100.0 × 2.0–2.5 µm, always 1-septate	Aborted: sometimes present; Fertile: always globose, 14.0–21.5 µm diam.	hemispherical, spherical or ovoid, 2.5–12.0 × 2.0–12.0 µm	hemispherical, 5.5–9.0 µm in diam.	globose, 2.0–3.0 µm in diam.		Adamcik et al. (2015)

Species	Colonies	Sporangiophores	Sporangia	Columellae	Apophyses	Sporangiospores	Giant cell	Reference
G. hydei	PDA: 25 °C 7 d 60.0–65.0 mm diam., circular, entire at edge, flat or effuse, dense, white;	up to 120.0 µm long, 1.6–3.2 µm wide, mostly unbranched, occasionally branched, mostly 1-septate	Fertile: globose to subglobose, 10.5–18.8 × 10.0–17.5 µm	hemispherical, sometimes tiny, 1.7–4.7 × 2.2–6.3 µm	cuboid-shaped with truncate at the base, 2.5–3.9 × 3.5–5.1 µm; cup-shaped rounded at the base, 2.7–6.2 × 3.8–7.8 µm; cup-shaped truncate at the base, 3.7–7.3 × 3.8–7.3 µm	reniform, 2.4–3.8 × 1.5–2.3 µm, ellipsoidal to fusiform, 2.6–3.4 × 1.8–3.4 µm	globose, guttulate, up to 25.0 µm diam.	Doilom et al. (2020)
G. inconstans	PDA: dark 25 °C 7 d 15.6–18.4 mm diam., white, regular at edge, cottony, in reverse milky white	unbranched or branched 2–3 times, 1.7–3.9 µm wide, mostly aseptate	Aborted: existence; Fertile: spherical, 8.8–21.4 µm diam.	mostly hemispherical, 1.2–2.4 × 2.0–3.9 µm, sometimes spherical, 3.2–7.2 × 3.4–7.2 µm	variously shaped, mostly long fusiform, 7.6–17.4 × 4.7–5.4 µm, sometimes oval-shaped, 5.5–8.8 × 4.4–6.3 µm, rarely egg-shaped, 5.0–6.4 × 4.2–5.7 µm	ovoid, 2.7–4.9 × 1.8–3.5 µm, reniform, 3.1–4.1 × 2.0–4.5 µm, some subcircular, 2.4–4.1 µm, occasionally irregular, 5.0–8.0 × 2.5–3.2 µm	intercalary, globular, 4.2–8.0 µm diam.	This study
G. koreana	PDA: 25 °C 7 d 31.5–33.0 mm diam., light white at first, cotton white with age, reverse from light-coloured to white	2.5–2.8 µm wide, mostly branched, 1-septate	Fertile: globose, 12.3–15.5 × 12.4–15.6 µm diam.	hemispherical, 1.2–2.3 × 2.6–3.3 µm	typically pyriform, 5.4–6.5 × 5.9–7.1 µm	mostly bean-shaped, 1.7–2.1 × 2.1–2.8 µm		Ariyawansa et al. (2015)
G. lacrispora	25 °C 13 d 50.0 mm in diam., 1–3 mm high, thickly floccose to felty, irregular at edge, at first white, then grey or pale grey, later pale wine colour	up to 6.5 µm wide, rarely septate	Aborted: sometimes present; Fertile: typically perfectly globose, 13.0–41.0 µm diam	dorsiventrally flattened to spherical, 2.5–13.0 × 4.5–20.0 µm	hemispherical, 4.0–8.6 µm. in diam.	lacrymoid to narrowly napiform, 2.8-4.5 × 5.5-9.0 µm	intercalary, globose to irregular, often with vacuoles or oil droplets, 20.0-37.0 × 60.0 µm	Hesseltine and Ellis (1961)
G. multiramosa	PDA: dark 25 °C 7 d 21.6–25.6 mm diam., white, regular at edge, cottony in centre, reverse milky white	unbranched or sympodially branched up to 7 times, 4.7–128.4 × 2.6–3.9 µm, usually 1-septate, occasionally containing a line of oil droplets	Aborted: ovoid, 9.6 × 6.2 µm diam.; Fertile: spherical, 15.5–23.2 µm diam.;	mostly hemispherical, 3.6–5.7 × 8.0–9.8 µm, sometimes sub-hemispherical, 3.0; –3.9 × 7.6–10.0 µm	mostly hemispherical, 4.4–5.6 × 8.5–9.0 µm, partially cup-shaped,4.6–7.0 × 8.5–10.0 µm	subspherical, 1.7–2.6 µm, ovoid, 2.6–3.3 × 1.7–2.3 µm, few reniform, 2.7–3.4 × 1.3–1.9 µm	globular, sub-spherical, 3.0–6.7 µm diam.	Wang et al. (2023a)
G. multispora	PDA: 27 °C 10 d 80.0 mm diam., 10.0 mm high, from white to yellowish, in reverse crusty, yellow	unbranched or sympodially branched, 2–3 in whorls and swollen on the base, 1 to several septate	Fertile: globose, 12.0–17.0 µm diam.	hemispherical, 2.0–4.5 × 2.0–4.0 µm	pyriform to subglobose, 8.0–12.0 × 7.0–9.5 µm	ellipsoid, fusiform, cylindrical, reniform subglobose to globose or irregular, 2.5–3.5 × 1.5–2.5 µm		Zhao et al. (2023)
G. namwonensis	MEA:25 °C 7 d 55.0 mm diam. (28 °C 5 d 90.0 mm diam), white, in reverse cream	simply or sympodially or monopodially branched, up to 1 mm long and 5.0 µm wide, in whorls of 2 or 3 times, mostly 1-septate	Aborted: sometimes formed; Fertile: globose, up to 30.0 µm diam.	globose, subglobose, 3.5–7.0 µm diam., hemispherical,; 1.8–5.5 × 2.5–8.5 µm, nipple-like, ellipsoidal, 2.0–3.8 × 2.0–5.0 µm	globose (2.5–)5.0–9.5(–12.0); µm, subglobose and ellipsoid, some with a truncated base,; 7.5–14.5 × 5.5–12.0 µm	reniform, ellipsoidal, some ovoid, 2.5–3.5 × 1.7–2.5 µm, rarely irregular, up to 6 × 2.5 µm	globose, subglobose and branched	Crous et al. (2020)
G. oleae	PDA: dark 25 °C 7 d, 16.3–17.0 mm diam., white, regular at edge, cottony in centre, inreverse milky white	unbranched or branched 3–4 times, 7.0–96.8 × 0.9–3.5 µm, mostly aseptate, sometimes 1-septate	Aborted: 7.0–7.8 µm diam.; Fertile: spherical, 8.8–24.5 µm diam.;	mostly sub-spherical or ovoid, 2.6–5.2 × 3.2–6.5 µm, sometimes hemi-spherical, 0.4–3.3 × 2.8–5.3 µm	pear-shaped, 4.4–5.6 × 8.5–9.0 µm, cup-shaped, 4.6–7.0 × 8.5–10.0 µm, elliptical or subspherical, 2.7–8.0 × 2.8–9.1 µm	ovoid, 2.40–3.34 × 1.51–2.35 µm, reniform, 2.58–4.99 × 1.48–2.24 µm	terminal, globular, sub-spherical, 3.2–6.5 µm diam.	Wang et al. (2023a)

G. orasabula	SMA: 25 °C 5 d, 33.0–35.0 mm, initial white, later off-white, irregular at edge, in reverse white	35.0–200.0 × 2.5–4.0 µm, simply branched 1–3 times	Fertile: globose to subglobose or calabash vase-shaped, 12.0–20.0 × 12.5–22.0 µm	hemispherical, 2.0–3.0 × 3.0–4.0 µm	globose, subglobose to pyriform, 5.0–10.0 × 4.5–8.5 µm	mostly bean-shaped, 2.0–3.5 × 2.0–2.5 µm		Li et al. (2016)
G. pamphilae	PDA: dark 25 °C 7 d 18.3–22.3 mm in diam., white, regular at edge and cottony in centre, in reverse milky white	unbranched or branched 1–2 times, 3.7–154.9 × 1.4–4.1 µm, mostly aseptate, occasionally 1- or 2-septate	Aborted: existence; Fertile: spherical, 13.8–30.8 µm diam.	mostly hemispherical, 1.8–4.7 × 2.0–7.7 µm, sometimes arc-shaped, 0.5–1.6 × 3.3–4.6 µm, spherical, 4.8–6.4 × 5.9–6.9 µm	spherical, 5.7–8.1 × 5.6–9.0 µm, ellipsoidal, 4.8–6.9 × 4.8–6.1 µm	reniform, 3.0–5.5 × 1.8–3.4 µm, ovoid, 2.5–5.6 × 1.8–3.7 µm	intercalary, globular, 4.0–8.1 µm diam	This study
G. pedratalhadensis	PDA: 25 °C 7 d 5.5 mm high, 45.0 mm diam., white, irregular at edge, in reverse pale	sympodially branched 1–2 times, 9.5–30.0 × 2.5–7.0 µm, mostly 1-septate below sporangia, rarely two or more septate	Aborted: existence; Fertile: globose 17.0–35.0(40.0) µm diam.	mostly hemispherical, some short hemispherical or subglobose, 5.0–15.0 × 4.0–21.5 µm	vasiform, short or long, 5.0–15.0 × 4.5–15.0 µm	bean-shaped, 2.5–3.5 × 1.5–2.5 µm, rarely irregular, 2.5–3.5 × 2.0–3.0 µm		de Freitas et al. (2020)
G. pingtangensis	PDA: dark 25 °C 7 d 19.4–22.8 mm diam., white, cottony, in reverse milky white	unbranched or sympodially branched 1–4 times, 1.4–5.9 µm wide, aseptate or 1-septate	Aborted: existence; Fertile: spherical, 14.2–27.1 µm diam.;	mostly hemispherical, 2.3–4.0 × 2.8–6.9 µm, some arch-shaped, 0.9–1.5 × 4.1–4.9 µm, spherical, 4.4–6.0 × 5.1–6.9 µm	mostly oval-shaped, 7.1–19.8 × 6.9–15.9 µm, some bowling pin-shaped, 15.6–17.5 × 8.5–9.4 µm, egg-shaped, 4.6–9.8 × 3.6–8.7 µm	mostly ovoid, 2.8–3.9 × 2.0–2.5 µm, some reniform, 2.9–3.6 × 1.9–2.4 µm, spherical, 2.1–2.7 µm, occasionally large irregularly shaped, 4.8–6.2 × 2.1–2.8 µm	intercalary, globular, 5.2–6.8 µm diam.	This study
G. qichaensis	PDA: dark, 25 °C 7 d 20.3–22.7 mm diam., white, cottony, regular at edge, in reverse milky white	unbranched or branched 1–2 times, 17.3–141.2 × 0.7–4.3 µm, usually aseptate, occasionally 2-septate	Aborted: ovoid,12.2–13.7 µm in diam.; Fertile: spherical, 7.9–36.7 µm diam.	ellipsoidal, 0.8–6.5 × 1.2–8.1 µm, sometimes sub-hemispherical to curved, 1.0–2.0 × 2.5–4.5 µm	mostly pear-shaped to oval, 4.6–13.4 × 3.4–10.7 µm, partially elliptical or sub-spherical, 6.0–11.3 × 4.8–9.0 µm	mostly ellipsoidal, 3.0–4.2 × 2.1–2.8 µm, sometimes reniform, 2.8–3.7 × 2.3–2.8 µm, few spherical, 2.4–3.3 µm	intercalary or terminal, globular, sub-spherical, 3.5–6.7 µm diam.	Wang et al. (2023a)
G. reniformis	PDA: dark 25 °C 7 d 19.7–20.9 mm diam., white, regular at edge and cottony in centre in reverse milky white	unbranched or branched 1–3 times, 3.4–157.9 × 0.8–3.4 µm, mostly aseptate, occasionally 1- or 2-septate	Aborted: gourd-shape, 15.0–19.9 × 3.1–10.9 µm; Fertile: spherical, 7.9–26.0 µm diam.	mostly elliptic, 1.7–4.6 × 1.4–5.2 µm, sometimes sub-hemispherical, 1.4–2.6 × 3.3–4.9 µm	pear-shaped, 3.3–8.5 × 3.0–7.3 µm, ellipsoidal, 4.6–10.1 × 2.9–7.8 µm	mostly reniform, 2.8–3.5 × 1.8–2.3 µm, ovoid, 3.1–3.37 × 1.7–2.0 µm	intercalary, globular, 3.5–10.0 µm diam.	This study
G. sichuanensis	PDA: 25 °C 14 d 4.0–5.0 mm high, 67.0–68.0 mm diam., white, regular at edge, in reverse grey	solitary or simply branched, 28.0–46.5 × 1.0–3.0 µm, 1- or 2-septate	Fertile: globose, subglobose, 10.5–26.5 µm diam.	hemispherical, 1.5–3.5 × 1.0–3.0 µm	ellipsoidal to subglobose, 4.5–8.5 × 4.5–6.0 µm in diam.	reniform, ovoid or ellipsoidal, 1.5–2.0 × 1.0–1.5 µm		Zhang et al. (2019)
G. zunyiensis	PDA: 25 °C 14 d 3.0–6.0 mm high, 70.0–75.0 mm diam., white, villiform, irregular at edge, in reverse grey-white	1.5–4.0 µm wide, branched several times, usually aseptate	Fertile: subglobose to globose, 11.0–19.5 µm diam.	hemispherical and globose, 2.0–3.0 × 3.5–7.0 µm	subglobose, 3.5–9.5 µm, conical-cylindrical, 4.0–7.0 × 5.0–9.0 µm	subglobose, reniform, 1.5–2.0 × 2.0–3.5 µm		Dong et al. (2019)

These significant morphological differences, coupled with those phylogenetically independent clades, ensure their novelty (Wang et al. 2023a). As for *G. pamphilae*, two strains were grouped into an independent separate clade and there are only two base pairs of difference in ITS rDNA sequences. As no morphological descriptions were provided for *G. pamphilae* in its protologue, we classified the two isolates together as the new record species of *G. pamphilae* only based on molecular phylogenetic analyses.

In summary, the molecular phylogenetic and morphological results support the identification of the six new species for the 12 strains cultured in this study, namely *G. abortosporangia*, *G. reniformis*, *G. apophysata*, *G. bawanglingensis*, *G. pingtangensis*, *G. inconstans* and two strains as new record species of *G. pamphilae*, complementing the morphological description of *G. pamphilae*. TFE, ACT and RPB1 protein-coding sequences were newly added to construct the phylogenetic evolutionary tree and the results were basically consistent with ITS+LSU results. The morphology of members of the genus *Gongronella* was systematically described herein, with a morphological description table being established for the described strains of *Gongronella* and the new strains described in this study (Table 4).

Acknowledgements

We thank Zhao-Xue Zhang (Shandong Agricultural University), Xin-Yi Wang (Shandong Normal University) and Shu-Bin Liu (Beijing Forestry University) for soil collection.

Conflict of interest

The authors have declared that no competing interests exist.

Ethical statement

No ethical statement was reported.

Funding

This study was supported by the National Natural Science Foundation of China (Nos. 32170012, 32300011, 32470004), Ji'nan City's 'New University 20 Policies' Initiative for Innovative Research Teams Project (202228028), Innovative Agricultural Application Technology Project of Jinan City (CX202210) and Key Technological Innovation Program of Shandong Province, China (2022CXGC020710)

Author contributions

Y.X. Wang took charge of the microscopy, DNA sequencing, data analyses and drafted the paper; H. Zhao made specimens, proposed new species and revised the paper; Y. Jiang, Xin-Y. Liu and M.F. Tao collected samples and isolated cultures; Xiao-Y. Liu proposed new species, revised the paper and provided funding.

The combined ITS+LSU+TEF+ACT+RPB1 sequence matrix used in this study

Authors: Yi-Xin Wang

Data type: fas

Explanation note: The sequence matrix included 43 strains in 25 species of *Gongronella*, with *Cunninghamella echinulata* CBS 156.28 as outgroup. A total of 4,080 characters comprised ITS rDNA (1–989), LSU rDNA (990–1967), TEF rDNA (1968–2172), ACT rDNA (2173–2948) and RPB1 rDNA (2949–4080). Among them, there were 2866 constant, 562 variable but parsimony non-informative and 652 parsimony informative characters.

Abstract

In this study, we assessed the phylogenetic relationships among members of *Ceratostomella* and the morphologically similar genus *Xylomelasma*, currently classified within the Sordariomycetes. Our phylogenetic analyses, utilising three and five gene markers, revealed that species from these two genera are congeneric, supporting the transfer of *Xylomelasma* to *Ceratostomella*. Consequently, we propose two new combinations: *C. sordida* **comb. nov.** and *C. novae-zelandiae* **comb. nov.** In addition, we identified two cryptic species within the *C. sordida* species complex, which are described as *C. crypta* **sp. nov.** and *C. melanospora* **sp. nov.** Traditional micromorphological characters have proven insufficient for differentiating these new species; however, they are clearly distinguishable by molecular data, particularly using the internal transcribed spacer region ITS1-5.8S-ITS2 (ITS) of the nuclear rRNA cistron, and genes encoding the second largest subunit of RNA polymerase II (*rpb2*), and translation elongation factor 1-α (*tef1-α*) as primary and secondary barcodes. This study provides new insights into the morphological characteristics of *Ceratostomella*, identifying the ascogenous system as an important diagnostic trait at the generic level, which distinguishes *Ceratostomella* from morphologically similar fungi. *Ceratostomella* is currently recognised with eight species. We also investigated the relationship between *Ceratostomella* and the closely related *Barbatosphaeria*. The lack of statistical support in the Maximum likelihood analysis is discussed and the inclusion of *Ceratostomella* in Barbatosphaeriaceae is not supported. *Ceratostomella* is accepted as a genus *incertae sedis*, while Barbatosphaeriaceae remains a monotypic family. The global diversity of *Ceratostomella* is inferred from metabarcoding data and published field observations. Biogeographic analysis indicates that members of *Ceratostomella* are widespread, found in soil and decaying wood, as well as in air, dust, roots, shoots, and water across temperate, subtropical and tropical regions in both the Northern and Southern Hemispheres. We are concurrently publishing whole-genome analyses of three ex-type strains of *Ceratostomella*, i.e. *C. crypta*, *C. melanospora* and *C. sordida*. This effort aims to establish a new standard for high-quality taxonomic studies, which, in accordance with current trends, should incorporate whole-genome sequencing data for future research and application. Our findings underscore the importance of integrating morphological, biogeographic and molecular data for accurate species delineation and highlight the complexity within the genus *Ceratostomella*.

Introduction

Ceratostomella (Saccardo 1878) was introduced to encompass species with simple diagnostic features, such as dark rostrate ascomata and hyaline, aseptate ascospores. According to MycoBank (Crous et al. 2004), 111 species have historically been assigned to this genus. However, the following studies have revealed that *Ceratostomella* is phenotypically more diverse than previously thought (e.g. Sydow and Sydow 1919; Elliott 1923; Melin and Nannfeldt 1934; Moreau 1952; Hunt 1956; Booth 1957; Dennis 1988; Samuels and Barr 1997; Réblová 2006; De Beer et al. 2013; Réblová et al. 2018). It includes taxa with both evanescent and persistent asci, as well as hyaline or pigmented ascospores. Additionally, it encompasses various types of interthecial filaments and, where known, asexual morphs characterised by annellidic, holoblastic, phialidic, and tretic conidiogenesis. The enormous species variability within *Ceratostomella* has posed a challenging task for mycologists, who have made numerous attempts to classify its species. Various studies using molecular data (see below) have demonstrated that *Ceratostomella* represents a heterogeneous species assemblage exhibiting phenotypic convergence. Despite their similar phenotypes, these species belong to several phylogenetically distinct lineages.

Of the numerous species ascribed to *Ceratostomella*, only a handful represents the core of the genus. Réblová (2006) redefined *Ceratostomella* through comparative morphology and phylogenetic analyses of ribosomal DNA sequences from two representative species, *C. cuspidata* and *C. pyrenaica*. Molecular data for the lectotype species, *C. rostrata*, designated by Clements and Shear (1931), are not available. *Ceratostomella* is characterised by non-stromatic perithecial ascomata with an upright cylindrical, sulcate neck, thick leathery to carbonaceous ascomatal wall, persistent clavate asci arising from supportive, discrete ascogenous cells, usually inconspicuous apical annulus, broadly cellular paraphyses, and brown, aseptate, suballantoidal, irregularly ellipsoidal, globose or reniform ascospores arranged in fascicle or 2–3-seriately within the ascus. The asexual morphs are unknown, and the axenic cultures derived from ascospores remained sterile. *Ceratostomella* thrives in strongly decayed wood or decaying *Polyporales* basidiomata and is primarily distributed in temperate regions of both hemispheres. The genus was classified as *incertae sedis* within *Sordariomycetidae* with four species accepted (Réblová 2006), and later, together with *Barbatosphaeria* and *Xylomelasma*, placed in the family Barbatosphaeriaceae by Zhang et al. (2017).

The revision of other *Ceratostomella* species with persistent asci prompted their reclassification in several unrelated genera within Sordariomycetes. These include *Barbatosphaeria* in Barbatosphaeriaceae (Réblová 2008; Réblová et al. 2015b), *Calyptosphaeria*, *Lentomitella*, *Spadicoides* and *Torrentispora* in *Xenospadicoidales* (Réblová et al. 2018), *Ceratosphaeria* in *Magnaporthales* (von Niessl 1876), *Chaetosphaeria* in Chaetosphaeriales (Booth 1957; Huhndorf and Fernández 2005), *Clohiesia* in *Annulatascales* (Réblová et al. 2018), *Daruvedia* in *Pyrenulales* (Dennis 1988), *Natantiella* (*incertae sedis*) (Réblová and Štěpánek

2009), *Jattaea* and *Togniniella* in Calosphaeriales (Réblová et al. 2004, 2015a; Réblová 2011), *Phaeoacremonium* in Togniniales (Gramaje et al. 2015), *Phomatospora* in *Phomatosporales* (Réblová et al. 2018), *Pseudorhynchia* in *Hypocreales* (Samuels and Barr 1997), and *Wallrothiella* in *Amplistromatales* (Réblová and Seifert 2004). Other species with evanescent asci and hyaline ascospores have been reclassified into several genera such as *Ceratocystis*, *Huntiella* and *Thielaviopsis* of *Microascales* and *Ceratocystiopsis*, *Grosmannia*, *Leptographium*, *Ophiostoma* and *Pesotum* of *Ophiostomatales*; these species including their synonymy are listed in De Beer et al. (2013, 2014). Unravelling the phylogenetic relationships of many other *Ceratostomella* species remains a complex task. This complexity arises from the lack of living cultures, insufficient diagnoses, ambiguous or lost holotypes, and the scarcity of recent collections. The entire taxonomic history of *Ceratostomella* was detailed in Réblová et al. (2018).

Xylomelasma (Réblová 2006) is remarkably similar to *Ceratostomella* in both morphology and ecology. The genus was typified by *X. sordida*, and *X. novae-zelandiae* was accepted as a second species. Both genera share similar ascospores and persistent asci that float freely within the centrum at maturity, robust paraphyses, rostrate non-stromatic ascomata with thick wall and occasional occurrence of Munk pores in the wall cells. In addition, they exhibit identical ascogenous apparatus, consisting of oval, clavate or obclavate, discrete cells from which asci arise as an outgrowth. *Xylomelasma* was distinguished from *Ceratostomella* by its ellipsoidal ascospores that are obliquely uniseriate, occasionally biseriate in the ascus, more or less cylindrical paraphyses, distinct apical annulus and ascomata with both sulcate and non-sulcate necks. Based on single-gene nuclear large and small subunit rDNA (LSU and SSU) phylograms, *Ceratostomella* and *Xylomelasma* were shown to be closely related, although they did not form a monophyletic clade (Réblová 2006). However, in the phylogenetic analyses based on the concatenated data set of LSU, SSU, and the second largest subunit of RNA polymerase II (*rpb2*) DNA sequences, a strongly supported relationship between the two genera was confirmed (Réblová et al. 2018). Currently, *Xylomelasma* contains four species, including *X. moderata* (Vassiljeva and Stephenson 2014) and *X. shoalensis* (Hernández-Restrepo et al. 2016).

During a survey of ascomycetes, we collected specimens of *C. cuspidata* and *C. pyrenaica* from Belgium and New Zealand, along with four collections preliminarily identified as *X. sordida* from wood in advanced stages of decay in the Czech Republic, and from a swab from generating station in the USA. Axenic cultures were derived from all collections. Furthermore, we re-examined the holotype of *X. novae-zelandiae*, which lacks a living culture as the ascospores never germinated *in vitro*, and we successfully extracted DNA from the ascomata.

The aim of this study is to investigate the relationships between *Ceratostomella* and *Xylomelasma*, as well as among the four '*X. sordida*' strains isolated by us, using comparative morphological studies and novel DNA sequences. Additionally, we sought to re-evaluate the morphological traits originally used to delimit both genera. To achieve this, we generated new sequences for nuclear rDNA ITS1-5.8S-ITS2 (ITS barcode), nuclear LSU and SSU rDNA, *rpb2*, and the intermediate section of the coding region of translation elongation factor 1-α (*tef1-α*) from all available ex-type and non-type strains of *Ceratostomella* and *Xylomelasma* and subjected them to phylogenetic analyses.

In our integrative taxonomic approach, we combine both phylogenetic and morphological data. With the capability of utilising GlobalFungi (Větrovský et al. 2020), we also incorporate geographical and ecological information. A crucial next step in advancing taxonomic standards and refining fungal classification is the concurrent publication of whole-genome sequence (WGS) data for type strains. This approach allows for more comprehensive comparisons between taxa, including with those so-called 'fungal dark taxa'—fungi that lack observable morphological structures, cannot be cultured under laboratory conditions, and are primarily detected through DNA sequencing, particularly via environmental metabarcoding (Nilsson et al. 2019). The current topic of significant discussion is the potential introduction of DNA-based typification (e.g. Nilsson et al. 2023), with WGS data serving as an alternative typification material. For such a system to function effectively, WGS data must also be available for the currently described diversity. In response to the call by Zhou (2024), we publish short-read WGS data for representative strains of *Ceratostomella*, supporting this emerging trend in fungal taxonomy.

Materials and methods

Fungal strains and morphological studies

Material was obtained from temperate regions in both the Northern and Southern Hemispheres, including a swab from the USA and collections on wood from temperate broadleaf and mixed forests in Belgium, Czech Republic, and New Zealand. Dried specimens were deposited into the Fungarium of the Institute of Botany CAS (**PRA**) in Průhonice, Czech Republic and New Zealand Fungarium (**PDD**) in Auckland, New Zealand. Cultures were deposited in Westerdijk Fungal Biodiversity Institute (**CBS**) in Utrecht, the Netherlands, and Culture Collection of Fungi (**CCF**), Faculty of Science, Charles University in Prague, Czech Republic. Other herbarium material was obtained from Fungarium of the Illinois Natural History Survey (**ILLS**) in Champaign, Illinois, USA. Along with our collections and literature references, data on the host and geographic distribution of the species studied were obtained from the MyCoPortal (http://www.mycoportal.org/portal/index.php, Miller and Bates 2017, accessed on October 14, 2024). Taxonomic novelties were registered in MycoBank. Table 1 presents the studied strains, their sources, and the GenBank accession numbers for the sequences obtained in this study.

Structures of the fungi on the host and living cultures were examined with an Olympus SZX12 dissecting microscope (Olympus America, Inc., Melville, NY, USA). Dry ascomata were rehydrated with water, and the gelatinous centrum was extracted using the tip of a needle. Microscopic preparations were mounted in 90% lactic acid, water, and Melzer's reagent. Measurements were taken from specimens mounted in Melzer's reagent and means ± standard deviation (SD) were calculated for sizes of asci and ascospores based on a minimum of 20–25 measurements. Microscopic observations were conducted using an Olympus BX51 light microscope. Nomarski differential interference contrast (DIC) and phase contrast (PC) were used for observations and measurements. Microphotographs were captured using an Olympus DP70 camera with Imaging Software Cell^D (Olympus). Colony macrophotographs were captured with a Canon EOS 77D digital camera with Canon EF 100 mm f/2.8L Macro IS USM

objective (Canon Europe Ltd., Middlesex, UK) with daylight spectrum 5500K 16W LED lights. Images were processed using Adobe Photoshop CS6 software (Adobe Systems, San Jose, CA, USA).

One isolate from a swab and five cultures derived from ascospores of fresh specimens were prepared in the context of this study; unfortunately, those of *C. cuspidata* IFBL 57.31 and *C. pyrenaica* PRA-21825 are no longer viable. Axenic cultures were prepared as outlined by Jurjević et al. (2015) and Réblová and Nekvindová (2023). In order to assess colony characteristics, diffusible pigments and growth patterns, strains were cultivated on cornmeal dextrose agar (CMD) (cornmeal agar, Oxoid Limited, Basingstoke, UK, supplemented with 2% w/v dextrose), MLA (Modified Leonian's agar) (Malloch 1981), oatmeal agar (OA), and potato-carrot agar (PCA) (Crous et al. 2019a). In addition, other nutrient media such as Modified cellulose agar (MCA), malt extract agar (MEA), and potato-dextrose agar (PDA) (HealthLink, Jacksonville FL, USA; currently Hardy diagnostics), were also used to incubate cultures. To measure the size of the colonies *in vitro*, an agar plug with 2-week-old mycelium was placed at the centre and at the edge of new 9 cm and 6 cm Petri dishes. Colony diameter was measured from cultures that were two and four weeks old. Colony characteristics were determined based on 4-week-old cultures incubated in the dark at

23 °C. To assess the growth at higher temperatures, the cultures were incubated at 30, 35, 37 and 41 °C on MEA, PDA, and OA for a period of two weeks. To induce sporulation, strains were also inoculated on cornmeal agar (CMA, Crous et al. 2019a) supplemented with sterile stems of *Urtica dioica* and exposed to alternating UV light and darkness in 12-hour intervals.

Gene markers, DNA extraction, PCR amplification, and sequencing

The relationships between *Ceratostomella* and *Xylomelasma*, as well as intraspecific and interspecific relationships within *Ceratostomella* were evaluated using five gene markers. These include the internal transcribed spacer ITS1-5.8S-ITS2 of the nuclear rRNA cistron used as a primary barcode for fungi (Schoch et al. 2012); the nuclear large subunit rDNA gene (D1–D3 domains, approximately 1800 base pairs) and the nuclear small subunit rDNA gene, which are commonly employed for studying relationships within the *Ascomycota* at the generic and higher taxonomic levels (e.g. Schoch et al. 2009). Additionally, genes encoding the second largest subunit of RNA polymerase II (DNA-directed RNA polymerase) and the intermediate section of the translation elongation factor 1-α were used, as they are effective in distinguishing interspecific relationships in fungi (e.g. Robert et al. 2011; Stielow et al. 2015).

Protocols for DNA extraction and PCR amplification of ITS, LSU, SSU, *rpb2*, and *tef1-α* were conducted following the methods described by Réblová and Nekvindová (2023). Automated sequencing was carried out by Eurofins Genomics Europe Sequencing Service (Cologne, Germany). Analyses of raw sequence data and assembly of sequence contigs were performed using Sequencher v. 5.4.6 (Gene Codes Corp., Ann Arbor, MI, USA). In Suppl. material 1, we provide the accession numbers of sequences for members of Sordariomycetes obtained from GenBank, most of which have been previously published in other studies (Ranghoo et al. 1999; Suh and Blackwell 1999; Huhndorf et al. 2004; Réblová and Seifert 2004; Réblová et al. 2004, 2011, 2015a,b, 2016, 2018, 2020, 2021; Miller and Huhndorf 2005; Réblová 2006, 2011, 2013; Shenoy et al. 2006, 2010; Yaguchi et al. 2006; Zhang et al. 2006, 2017; Arzanlou et al. 2007; Spatafora et al. 2007; Damm et al. 2008; Plattner et al. 2009; Réblová and Štěpánek 2009; Thongkantha et al. 2009; Ferrer et al. 2012; Jaklitsch et al. 2013; Untereiner et al. 2013; Klaubauf et al. 2014; Tsang et al. 2014; Hernández-Restrepo et al. 2016; Senanayake et al. 2016; Yang et al. 2017; Réblová and Štěpánek 2018; Song et al. 2018; Crous et al 2019b; Luo et al. 2019; Lu et al. 2020; Hyde et al. 2021).

The ex-type strains of *C. crypta* CBS 131683, *C. melanospora* CBS 147993 and *C. sordida* CBS 116000 were selected for whole-genome DNA sequencing. Genomic DNA was extracted from 5-day-old cultures grown on MEA agar plates using the NucleoSpin® Soil isolation kit (Macherey–Nagel, Düren, Germany). Library preparation (2 × 300 bp Illumina paired-end) was carried out, and sequencing was performed on a NextSeq 2000 instrument (Illumina) following the manufacturer's protocol. The quality of the raw sequencing data was assessed using FastQC v. 0.11.9 (Andrews 2010) (Accessed on 23 Aug. 2024), and low-quality reads were filtered out using Trimmomatic v. 0.39 (Bolger et al. 2014) based on the quality control results (FastQC 0.11.9). The high-quality reads were then assembled de novo using SPAdes v4.0.0 (Bankevich et al. 2012). Genome assembly quality was assessed using QUAST v. 5.2.0 (Gurevich

et al. 2013), and completeness was evaluated with BUSCO v. 5.7.1.1 (Seppey et al. 2019) against the fungi_odb10.2019-11-20 dataset. Genome annotation was conducted using the Funannotate pipeline v. 1.18.16 (Palmer and Stajich 2020) to predict and annotate gene models within the target genome. Functional annotation was performed using InterProScan v. 5.69-101.0 (Jones et al. 2014) and EggNOG-mapper v. 2.1.9 (Huerta-Cepas et al. 2019). The genome identities were confirmed by comparing extracted ITS barcode sequences.

Phylogenetic and barcode analyses

The gene sequences were aligned using MAFFT v. 7.487 (Katoh and Standley 2013) implemented in the CIPRES Science Gateway v. 3.3 (Miller et al. 2010) and manually corrected in BioEdit v. 7.1.8 (Hall 1999), if necessary. Phylogenetic analyses were executed using software packages available on the CIPRES Science Gateway v. 3.3. First, we conducted separate single-marker Maximum likelihood (ML) analyses with RAxML-HPC v. 8.2.12 (Stamatakis 2014). Since we did not detect any conflicting clades between these analyses, the individual sequence alignments were concatenated into two final alignments (deposited in TreeBASE, study number 31694) and subjected to phylogenetic analyses. Partitions, for which we assumed rate heterogeneity, were evaluated using MrModeltest v. 2.4 (Nylander 2004) to determine the best partitioning scheme for our datasets and to select the best-fit models under Akaike information criteria.

In the first phylogenetic analysis of LSU-SSU-*rpb2* sequences, the alignment comprised 107 ingroup strains and included a total of 4 676 characters including gap regions, with 2 452 unique character sites (RAxML). Eighty-six nucleotides (nt) at the beginning of LSU and 70 nt at the beginning of SSU were excluded from the analyses due to the incompleteness of many sequences retrieved from GenBank. Three members of the *Savoryellales* (*Hypocreomycetidae*), such as *Bactrodesmium abruptum*, *Bactrodesmium diversum*, and *Neoascotaiwania terrestris*, were selected as the outgroup, based on previous research and known relationships within the Sordariomycetes, and availability of molecular data (Réblová et al. 2020). The GTR+I+G best-fit model of nucleotide evolution was selected for each partition.

In the second phylogenetic analysis of ITS-LSU-SSU-*rpb2*-*tef1*-*α* sequences, the alignment included 11 strains representing 6 species of *Ceratostomella*, encompassing a total of 6 161 characters including gap regions, and 1 099 unique character sites (RAxML). Seventy nucleotides at the beginning of SSU were excluded from the analysis due to the incompleteness of many sequences. The outgroup was selected from members of Chaetosphaeriaceae, specifically *Curvichaeta curvispora* and *Menispora uncinata*, based on known relationships from the first analysis and the availability of DNA sequences. The following best-fit models of nucleotide evolution were selected for each partition: GTR+I for ITS, LSU, *tef1*-*α*; HKY+I for SSU; and GTR+G for *rpb2*.

The Maximum likelihood analysis was performed with RAxML-HPC v. 8.2.12 with a GTRCAT approximation. Statistical support for the nodes was determined by non-parametric bootstrapping (BS) with 1 000 replicates. The Bayesian Inference (BI) analysis was performed with MrBayes v. 3.2.7 (Ronquist et al. 2012). Two Bayesian searches were conducted using default parameters. The B-MCMCMC (Bayesian-Metropolis-coupled Markov chain Monte Carlo) analyses lasted until the average standard deviation of split frequencies was below

0.01, with trees saved every 1 000 generations with a burn-in of 25%. The BI and ML phylogenetic trees were compared visually in terms of topological conflicts between the supported clades. Nodes supported by values of ≥ 75% ML Bootstrap (BS) and ≥ 0.95 BI Posterior Probability (PP) were deemed well-supported. Phylogenetic trees were visualised in FigTree v. 1.4.3 (Rambaut 2010) and SeaView v. 5.0.5 (Gouy et al. 2010) and edited in Microsoft PowerPoint.

The identity/similarity for ITS, *rpb2* and *tef1-α* sequences of members of *Ceratostomella* was calculated using BioEdit. Histograms of intraspecific and interspecific distances were created for ITS, *rpb2* and *tef1-α* markers to illustrate the extent of overlap for each gene (the so-called barcode gap). A matrix of pairwise distances was computed in MEGA v. 11.0.13 software (Tamura et al. 2021) using the p-distance model with gap deletion (pairwise deletion option) (Kimura 1980). The histograms were plotted in GraphPrism v. 7.03 (Graphpad Software, La Jolla, California) using a bin size of 0.003 (ITS), 0.002 (*rpb2*) and 0.001 (*tef1-α*).

Biogeography assessment using published environmental sequences

The biogeography of six out of the eight known *Ceratostomella* species with available ITS sequences was examined following the workflow outlined by Réblová et al. (2022). We utilised the GlobalFungi database (Větrovský et al. 2020), release 5 (16.11.2023), which comprises 84 972 samples from 846 studies, encompassing 593 399 355 unique ITS1 or ITS2 sequences. Since the GlobalFungi database contains separate ITS1 and ITS2 sequences, we analysed these regions independently. To ensure consistency with the ITS spacers stored in GlobalFungi, which were originally extracted using the ITSx extractor (Bengtsson-Palme et al. 2013), we used the ITSx extractor implemented in the SEED2 platform (Větrovský et al. 2018) to extract the spacers from our data. To identify *Ceratostomella* species in GlobalFungi, we conducted an exact hit similarity search in the database with all unique ITS1 and ITS2 haplotypes from our study, searching for published environmental sequences that match in both length and sequence.

Results

Phylogenetic and barcode analyses

In the first phylogenetic analysis, based on a three-gene dataset (LSU-SSU-*rpb2*), we assessed the relationships among *Ceratostomella*, *Xylomelasma*, and representatives of the Sordariomycetes. Phylogenetic trees constructed through BI and ML analyses displayed broad congruence, with the ML tree depicted in Fig. 1. The nodes with support values ≥ 75% ML BS and ≥ 0.95 BI PP were considered well-supported. The phylogram revealed 40 well-supported lineages representing 33 families or orders and seven genera *incertae sedis* belonging to three major, strongly supported clades, i.e. *Diaporthomycetidae* (98% ML BS /1.0 PP), *Sordariomycetidae* (83/0.98) and *Sordariomycetidae incertae sedis* (95/1.0). Members of *Ceratostomella* and *Xylomelasma* formed a monophyletic, strongly supported and fully resolved clade (95%/1.0) in the *Sordariomycetidae incertae sedis*. This clade included two strains of *C. cuspidata* (ICMP 17629, IFBL 57.31), three strains of *C. pyrenaica* (CBS 117116, CBS 129343, PRA-21825), the ex-type strains of *X. sordida* CBS 116000 and *X. novae-zelandiae* PDD 81433, and

four new isolates initially identified as *X. sordida*. While the two *Ceratostomella* species formed a strongly supported subclade (100/1.0), the original representatives of *Xylomelasma* were not monophyletic. *Xylomelasma sordida* formed a species complex (98/1.0) as a sister to *Ceratostomella*, whereas *X. novae-zelandiae* clustered on a basal branch. These results support the conclusion that both genera are congeneric and that *Xylomelasma* represents a synonym of the older name *Ceratostomella*, with two new combinations proposed, *C. sordida* and *C. novae-zelandiae*. Four new strains acquired in this study represent two cryptic species that are morphologically indistinguishable from *C. sordida*. These strains are described below as *C. crypta* (ex-type strain CBS 131683, CBS 131684, CCF 5710) and *C. melanospora* (ex-type strain CBS 147993). Additionally, *X. shoalensis* holotype ILLS 76895 is shown to be conspecific with *C. sordida* CBS 116000, with their LSU (760 nt long fragment) exhibiting 99.2% sequence similarity. The *Ceratostomella* clade is a sister (62/0.99) to *Barbatosphaeria* (Barbatosphaeriaceae) (94/1.0), though this relationship is not statistically supported in the ML analysis. Other close relatives of *Ceratostomella* include members of the clade (94/1) containing *Ophiostomatales* (100/1) and *Natantiella ligneola* CBS 123470.

In the second phylogenetic analysis, we utilised a five-gene dataset (ITS-LSU-SSU-*rpb2*-*tef1-α*) to focus on the relationships among *Ceratostomella* species. Both ML and BI trees were congruent, with the ML tree shown in Fig. 2. Compared to the first analysis (Fig. 1), the *Ceratostomella* clade differed in the position of *C. novae-zelandiae*, which appeared on a separate branch as a sister (99/1.0) to the *C. cuspidata* and *C. pyrenaica* subclade (100/1.0). The *C. sordida* species complex consisted of three morphologically indistinguishable species that can be clearly differentiated by molecular data. The low sequence similarity of ITS, *rpb2*, and *tef1-α* markers, along with the high evolutionary divergence among these markers within the *C. sordida* species complex warrant the recognition of three distinct species, including the newly identified *C. crypta* and *C. melanospora*. *Ceratostomella crypta* was represented by three isolates in the phylogenetic analysis; the strain CBS 131684 exhibited the following sequence similarities with the ex-type strain and the other isolate CCF 5710: 99.6% in ITS, 100% in LSU, SSU, and *tef1-α*, and 99.8% in *rpb2*. *Ceratostomella sordida* and *C. crypta* exhibited sequence similarities of 89.3–90.8% in ITS, 90.4% in *rpb2*, and 96.3% in *tef1-α*. *Ceratostomella sordida* and *C. melanospora* showed similarities of 78% in ITS, 85.2% in *rpb2*, and 96.5% in *tef1-α*. *Ceratostomella crypta* and *C. melanospora* demonstrated similarities of 70–76.9% in ITS, 84.7–84.9% in *rpb2*, and 93.8% in *tef1-α*.

We recognised a clear barcoding gap in all three markers: ITS, *rpb2* and *tef1-α* (Fig. 3). Regarding species differences in genetic divergence among the three barcodes within the *C. sordida* species complex, the divergence was generally lower between *C. sordida* and *C. crypta* (ITS: 7.5–7.7%, *rpb2*: 9.6%, *tef1-α*: 3.6–3.7%) compared to the higher divergence encountered between *C. sordida* and *C. melanospora* (ITS: 23.7%, *rpb2*: 15%, *tef1-α*: 6.5%). The genetic divergence between the new species, *C. melanospora* and *C. crypta*, ranged from 6.2% in *tef1-α*, 15.1–15.3% in *rpb2* to 23.9% in ITS. The estimates of genetic divergences between *C. melanospora*/*C. sordida* and *C. melanospora*/*C. crypta* in ITS and *rpb2* were the highest within the *C. sordida* species complex. The estimates of evolutionary divergence are provided in the Suppl. material 2.

557 to 9491, with genome completeness, based on conserved fungal genes, between 98.5% and 98.9%. Genome sizes varied from 38.9 to 52.4 Mbp. The annotated genomes have been deposited in the NCBI database, and the quality and completeness of the assembled whole genomes are presented in Table 2.

Biogeography of *Ceratostomella*

Members of *Ceratostomella* thrive on decaying wood and decaying basidiomata of *Polyporales*. They have also been detected in environmental samples predominantly isolated from air and soil, as well as from deadwood, shoots, roots and water across various habitats. Representatives of the genus *Ceratostomella* are distributed worldwide, primarily in temperate regions of the Northern and Southern Hemispheres, with some occurrences in subtropical (*C. cuspidata*, *C. sordida*) and tropical (*C. sordida*) zones of Asia, Australasia, Europe and North America and South America. According to GlobalFungi, the most common species appears to be *C. sordida*, which is the only species found across various biomes in temperate, subtropical and tropical regions. *Ceratostomella sordida* was identified in 126 samples, compared to other species with known DNA sequences: *C. pyrenaica* (50 samples), *C. cuspidata* (28), *C. crypta* (10), *C. melanospora* (7), and *C. novae-zelandiae* (2). For detailed information, see Suppl. material 3.

Taxonomy

***Ceratostomella* Sacc., Michelia 1: 370. 1878.**

Xylomelasma Réblová, Mycologia 98: 87. 2006. Synonym.

Lectotype species. *Ceratostomella rostrata* (Tode) Sacc., Syll. Fung. 1: 409. 1882 (Lectotype designated by Clements and Shear 1931).

Description. *Sexual morph*. Ascomata perithecial, non-stromatic, venter globose to subglobose, superficial, semi-immersed or immersed, glabrous, roughened or tuberculate, dark brown to black, usually surrounded by sparse mycelium; hyphae growing out of the sides and bottom of the venter. Necks rostrate, central, cylindrical, straight to slightly flexuous, perpendicular or oblique to almost decumbent toward the substrate, sulcate or glabrous. Ostiolum periphysate. Ascomatal wall leathery to carbonaceous, two-layered. Outer layer consisting of brown, thick-walled cells, textura prismatica to textura angularis to textura epidermoidea, often with a distinct, external crustose layer of heavily pigmented, dark brown cells with opaque walls. Inner layer consisting of thin-

Figure 1. Maximum Likelihood phylogenetic tree of members of the Sordariomycetes based on analysis of LSU, SSU, and *rpb2* DNA sequences. Species names given in bold are taxonomic novelties; the newly acquired strains and those with novel sequences are highlighted in blue font; T, E and P denote ex-holotype, ex-epitype and ex-paratype strains; [a] paratype of *Cryptadelphia polyseptata*, [b] holotype of *Calosphaeriophora pulchella*, [c] holotype of *Poroconiochaeta discoidea*, [d] holotype of *Coniochaetidium ostreum*, [e] holotype of *Cryptendoxyla hypophloia*, [f] Nom. inval., Art. 36.1(c) (Melbourne), [g] holotype of *Jattaea prunicola*, and [h] holotype of *Diplorhinotrichum juncicola*. ner-walled, subhyaline to hyaline, elongated and compressed cells. Ascogenous hyphae with croziers, with several lateral and terminal dehiscent cells produced sequentially and simultaneously, from each ascogenous cell one ascus arises as an outgrowth. Paraphyses abundant, unbranched, septate, hyaline, broad-celled and constricted at the septa, wider near the base, tapering, apically free, longer than the asci, disintegrating with age. Asci unitunicate, persistent, clavate to cylindrical-clavate, short-stipitate, truncate to broadly rounded at the apex, tapering toward the base from the sporiferous part, floating freely within the centrum at maturity, with a shallow, sometimes indistinct, non-amyloid apical annulus, 8-spored. Ascus stipe usually contains non-refractive material deposited at the bottom part, visible after ascus dehiscence from the ascogenous cell. Ascospores variable in shape, suballantoid, ellipsoidal to irregularly ellipsoidal, globose or reniform, straight or curved, often flattened on one side, hyaline when young, becoming pale brown to brown before discharge from the ascus,

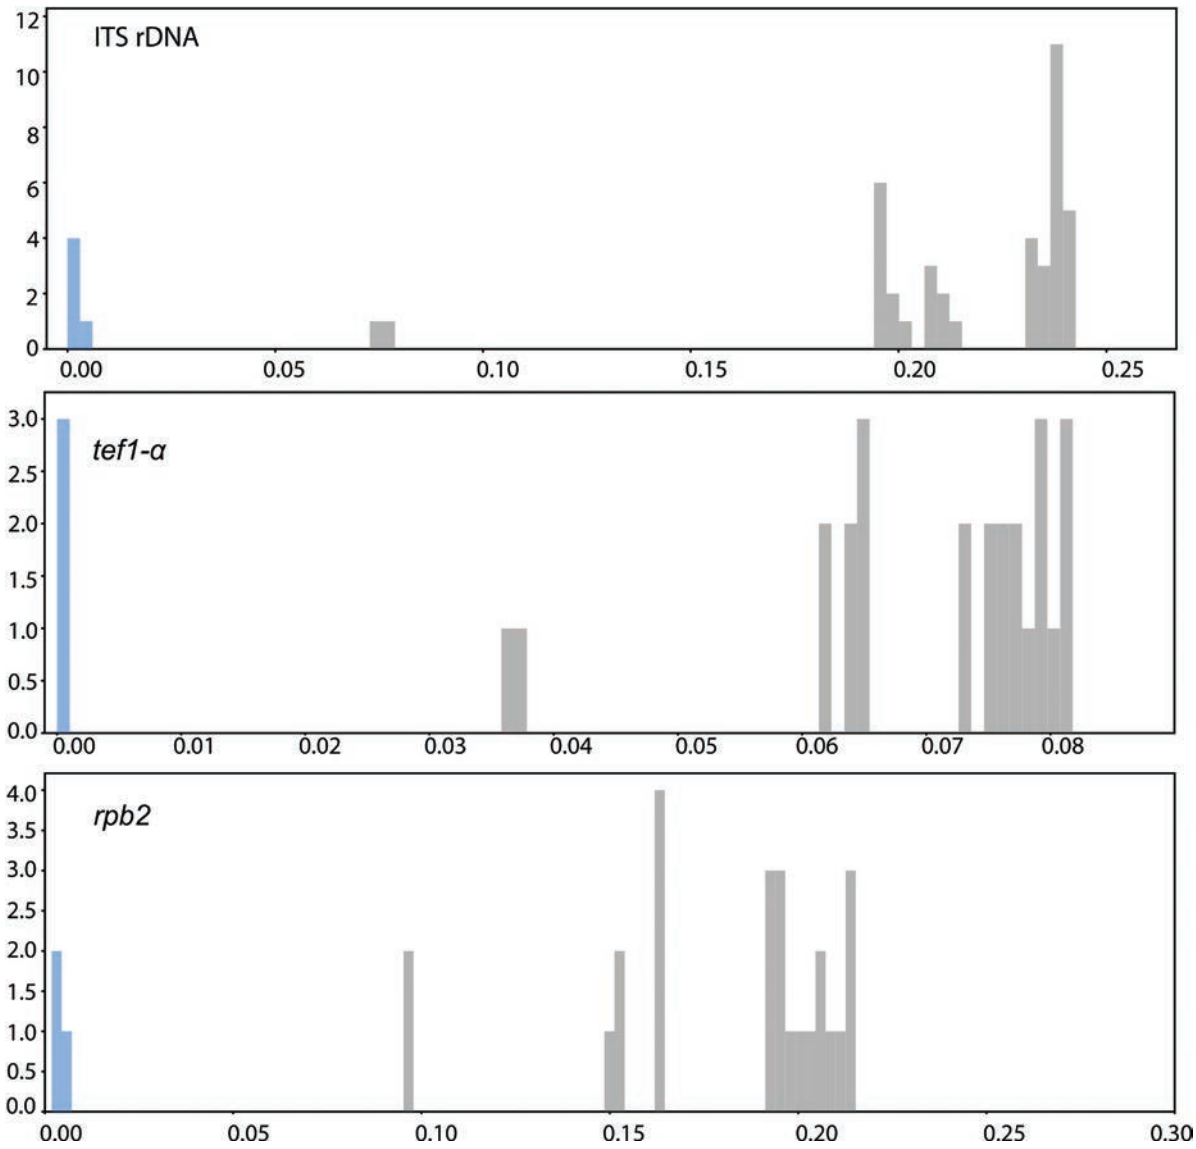

Figure 3. Barcoding gap. The frequency distribution graphs of the Kimura 2-parameter distances of ITS, *rpb2* and *tef1-α* DNA sequences (i.e. barcoding gaps). The intraspecific distances are shown as blue bars and interspecific distances as grey bars.

aseptate, smooth, sometimes with indistinct terminal pores at one or both ends, arranged in a fascicle in the upper part of the ascus or 2–3-seriate or uniseriate within the ascus. (Partially adopted from Réblová 2006.) ***Asexual morph*.** Hyphomycetous, dematiaceous; in culture only sterile mycelium was observed.

Accepted species. *Ceratostomella crypta*, *C. cuspidata*, *C. melanospora*, *C. novae-zelandiae*, *C. pyrenaica*, *C. rhynchophora*, *C. rostrata,* and *C. sordida*.

Notes. Species of *Ceratostomella* exhibit a variety of ascospore shapes, including suballantoid to reniform in *C. cuspidata*, suballantoid non-apiculate in *C. rostrata*, ellipsoidal slightly apiculate in *C. crypta*, *C. melanospora*, *C. rhynchophora*, and *C. sordida*, and ellipsoidal to oblong in *C. pyrenaica*. Réblová (2006) also described *Ceratostomella* sp. M.R. 2592, which has globose ascospores; however, this species lacks molecular data to confirm its placement in the genus. The key to identifying *Ceratostomella* species was provided by Réblová (2006). Table 3 displays morphological characteristics of *Ceratostomella* species accepted in the genus.

Table 3. Morphological characteristics of *Ceratostomella* spp.

Taxon	Ascomata size*	Munk pores	Neck	Asci size	Ascospores size	Shape	Sample (GF)**	Ref.
C. crypta	350–500	No	sulcate	66–77(–81.5) × 7.5–9.5(–10)	8.5–11 × (4–)4.5–5.5	ellipsoidal, slightly apiculate	10	1
C. cuspidata	380–500	Yes	sulcate	21–30 × (5–)6–7	4–5 × 2–3	suballantoid to reniform	28	2
C. melanospora	300–480	No	sulcate	63–78 × 6.5–8(–8.5)	(8–)8.5–10.5(–11) × 4–5	ellipsoidal, slightly apiculate	7	1
C. novae-zelandiae	310–340	No	smooth	50–60(–65) × 7–8(–9)	7–8 × (3.5–)4–5	ellipsoidal, slightly apiculate	2	2
C. pyrenaica	400–550	No	sulcate	(30–)33–40 × 5.5–7	7–9 × 3–4	ellipsoidal to oblong, slightly curved and apiculate	50	2
C. rhynchophora	500–650	No	sulcate	(33–)35–44 × 7–8.5(–10)	6–7 × (3.5–)4–5	ellipsoidal, slightly apiculate, sometimes flattened on one side	n/a	2
C. rostrata	650–750	Yes	sulcate	(26–)30–39 × 5–6	4.5–6 × 1.5–2	allantoid to suballantoid	n/a	2
C. sordida	490–550	Yes	sulcate	(58–)60–76(–81) × 7–10(–13)	9–12 × 4–6	ellipsoidal, slightly apiculate	126	2

* Size of ascomata (diam), asci and ascospores is given in µm.
**GF = GlobalFungi database; the number indicates the total number of samples with identical sequences detected in GlobalFungi.
n/a = data not available.

***Ceratostomella crypta* Réblová, Hubka & Jurjević, sp. nov.**
MycoBank No: 855703
Figs 4–6

Etymology. *Cryptus* (Latin) meaning hidden, secret; referring to cryptic nature of this species, which is morphologically indistinguishable from *C. melanospora* and *C. sordida*.

Type. Czech Republic • South Moravian Region, Břeclav district, obora Soutok near Lanžhot; on decaying deciduous wood; 23 Oct 2004; M. Réblová M.R. 2911 (holotype PRA-21820!, ex-type culture CBS 131683).

Description. *Sexual morph*. Ascomata non-stromatic, grouped, immersed with only necks protruding, sometimes partially erumpent with bases semi-immersed. Venter 350–500 µm diam, subglobose, upright, dark brown to black, with sparse brown, septate, slightly flexuous hairs 3.5–4.5 µm wide sparsely covering the sides and bottom. Neck 100–120 µm wide, up to 860 µm long, central, cylindrical, upright, tapering at the top, sulcate along the upper half or the whole length. Ostiole periphysate. Ascomatal wall fragile to leathery, 51–72(–82) µm thick, two-layered. Outer layer consisting of thick-walled, dark brown, polyhedral cells with opaque walls of textura prismatica, with several cells forming the external crustose layer ca. 9–14 µm thick, cells tend to be more flattened and paler towards the interior. Inner layer consists of several rows of thin-walled, hyaline, flattened cells. Paraphyses abundant, longer than the asci, becoming partially disintegrated with age, septate, slightly constricted at the septa, hyaline, 5–9.5 µm wide, wider near the base, tapering to ca. 3.5 µm. Asci 66–77(–81.5) × 7.5–9.5(–10) µm (mean ± SD = 74.9 ± 4.4 × 8.7 ± 0.8 µm), 57.5–71.5(–86) µm (mean ± SD = 65.8 ± 2.6 µm) long in the sporiferous part; asci containing mostly collapsed ascospores are generally smaller in size 61–71.5(–74) × 7–8.5 µm (mean ± SD = 66.4 ± 2.9 × 7.8 ± 0.6 µm), 50.5–59 µm (mean ± SD = 54.3 ± 3.5 µm) long in the sporiferous part, broadly rounded to truncate at the apex, cylindrical, with a short tapering stipe, apical annulus non-amyloid, 2.5 µm wide, 1–1.5 µm high, 8-spored. Ascospores 8.5–11 × (4–)4.5–5.5 µm (mean ± SD = 9.5 ± 0.7 × 5 ± 0.3 µm), ellipsoidal, slightly apiculate

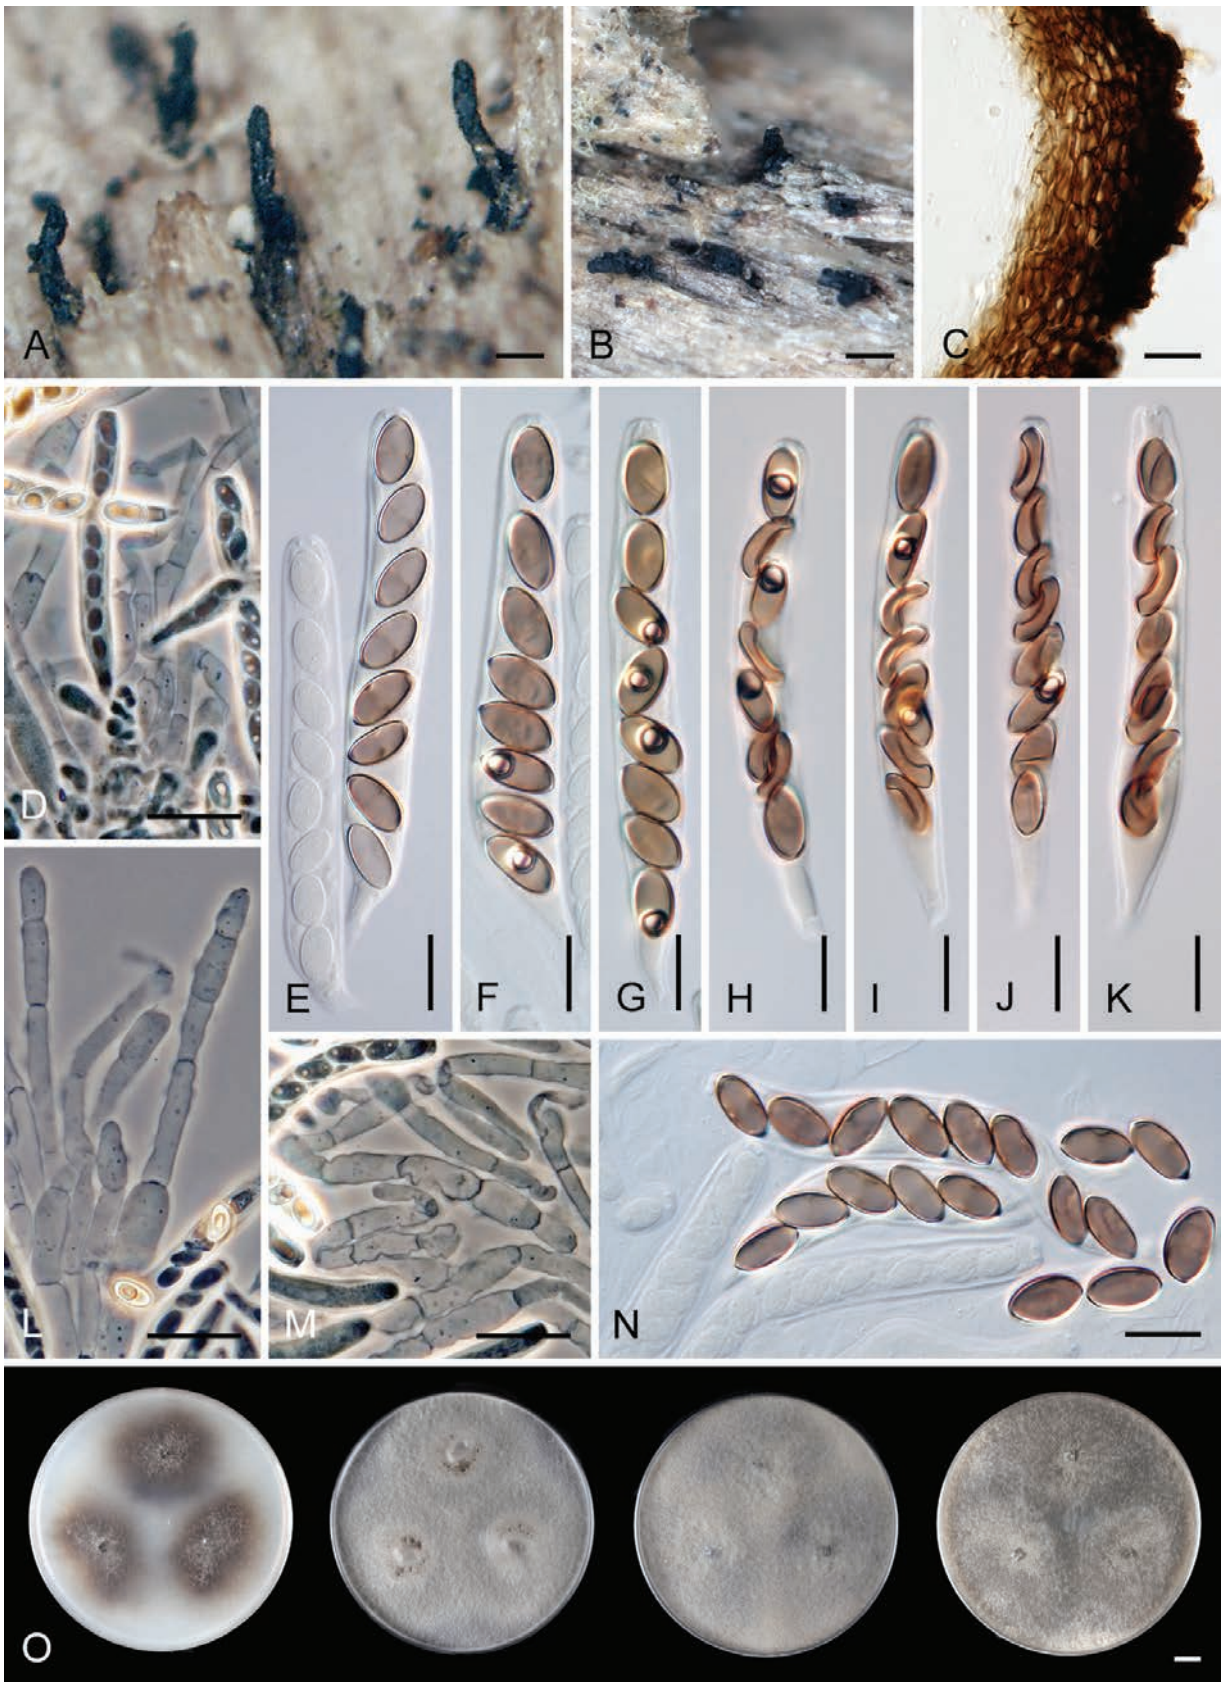

Figure 4. *Ceratostomella crypta* (**A–N** from holotype PRA-21820 **O** from ex-type strain CBS 131683) **A, B** ascomata **C** a longitudinal section of the ascomatal wall **D** asci with paraphyses and ascogenous cells **E–K** asci with ascospores **L, M** paraphyses **N** ascospores **O** colony morphology at 23 °C after 4 weeks on CMD, MLA, OA and PCA (from left to right). Images: on natural substrate (**A–N**). Scale bars: 500 µm (**A, B**); 20 µm (**C, D, L, M**); 10 µm (**E–K, N**); 1 cm (**O**).

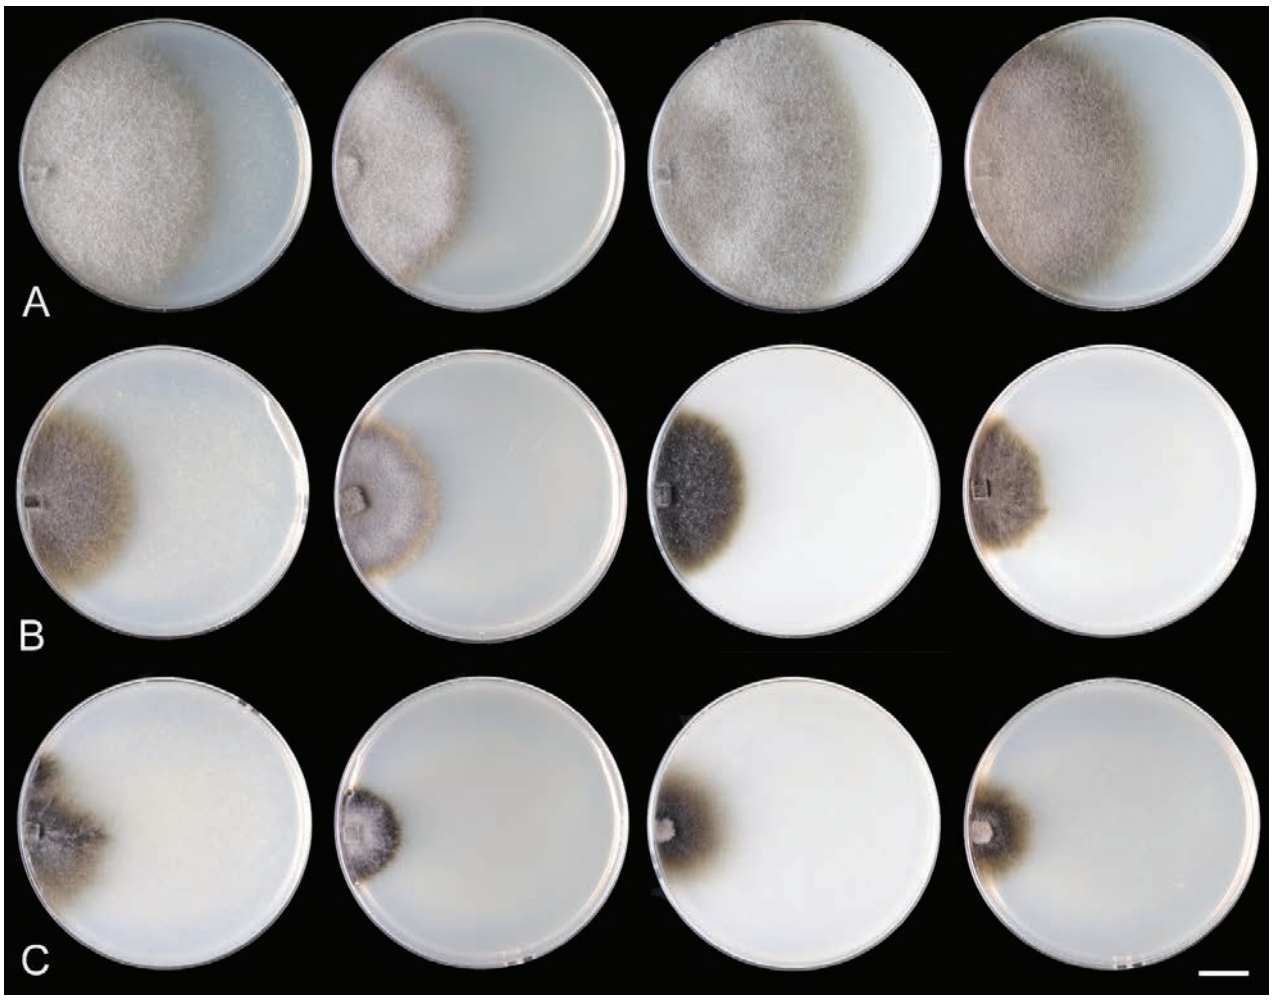

Figure 5. Growth rates *in vitro* of *Ceratostomella* spp. **A** *C. crypta* CBS 131683 **B** *C. sordida* CBS 116000 **C** *C. melanospora* CBS 147993. Colonies on CMD, MLA, OA and PCA (from left to right) after two weeks. Scale bar: 1 cm.

at both ends, brown, aseptate, smooth, with an inconspicuous germ pore at one or both ends, sometimes with one oil drop, often collapsing, obliquely uniseriate or partially overlapping within the ascus. ***Asexual morph*.** Unknown.

Characteristics in culture (after 2/4 wk at 23 °C). On CMD colonies 70–72 mm/mycelium fully covered the plate, circular, flat, margin effuse to fimbriate with a sparse growth, cobwebby, grey-brown, reverse of the same colour. On MLA colonies 50–51 mm diam/mycelium fully covered the plate, margin entire to fimbriate, circular, flat, margin entire, lanose, olivaceous grey, reverse dark olivaceous brown. On OA colonies 83–85 mm diam/mycelium fully covered the plate, circular, margin entire to fimbriate, lanose, olivaceous grey, reverse dark brown. On PCA colonies 62–64 mm diam/mycelium fully covered the plate, circular, flat, margin diffuse, cobwebby, grey-brown, reverse dark brown. Sporulation was absent on all media.

Temperature dependent growth at 30, 35, 37, 41 °C was assessed as colony diam on MEA, PDA, and OA, respectively, after a period of two weeks: 30 °C >90 mm/>90 mm/>90 mm, 35 °C >90 mm/>90 mm/>90 mm, 37 °C >90 mm/>90 mm/>90 mm, 41 °C 46–48 mm/40–41 mm/26–27 mm.

On MCA, colonies are effuse, with commonly submerged subhyaline hyphae that later become vein-like, ranging in colour from brown to dark olivaceous

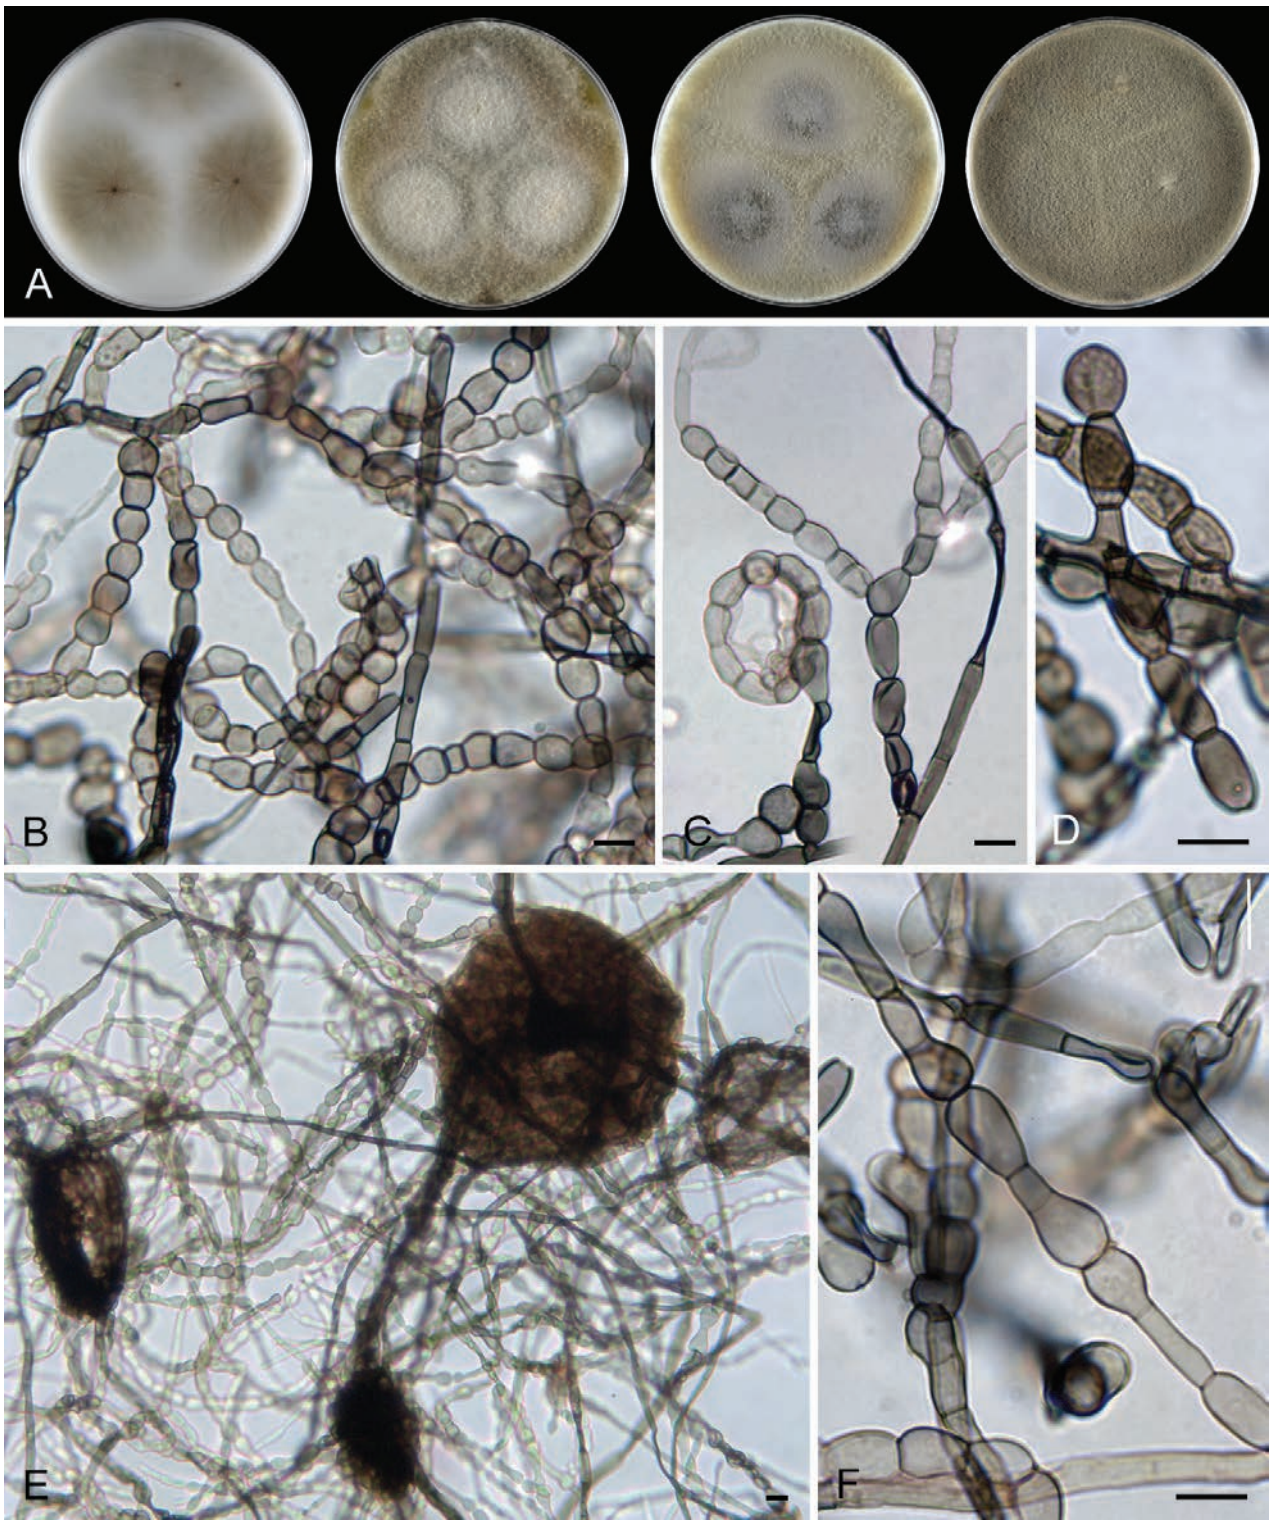

Figure 6. *Ceratostomella crypta* (CCF 5710) **A** colony morphology at 37 °C after 2 weeks on MCA, MEA, OA and PDA (from left to right) **B, D–F** pigmented monilioid hyphae on CA. **C** monilioid hyphae on MEA. Scale bars: 1 cm (**A**); 10 µm (**B–F**).

brown, 3–7 µm in diameter, smooth and septate, with occasional tuberose formations. These hyphae often branch to form monilioid hyphae composed of thick-walled cells, varying in shape from nearly rectangular to subglobose. Branching of monilioid hyphae often occurs at right angles, coiling hyphae are also present.

Additional specimens examined. Czech Republic • South Moravian Region: Břeclav district, obora Soutok near Lanžhot; on decaying deciduous wood; 23 Oct 2004; M. Réblová M.R. 2916 (PRA-21821, culture CBS 131684). USA • South Carolina: swab from generating station; Jul 2014; Ž. Jurjević 2471 (culture CCF 5710 = CBS 142809).

Habitat and geographical distribution. Saprobe on decaying deciduous wood in the Czech Republic; it was also isolated from a swab from generating station in the USA (South Carolina). According to GlobalFungi, the species is distributed predominantly in the temperate region of the Northern Hemisphere. Identical sequences were found in 10 samples isolated from air, sediment, soil, and water in various habitats including cropland, forest, shrubland, wetland, anthropogenic, and aquatic environments in the USA (California, Louisiana, North Carolina, and Tennessee).

Notes. Distinguishing *C. crypta* from other species within the *C. sordida* complex presents significant challenges. Nonetheless, *C. crypta* can be reliably differentiated through analysis of ITS, *rpb2*, and *tef1-α* sequences. Moreover, *in vitro* observations revealed that *C. crypta* demonstrates the highest growth rate within its species complex (Fig. 5). It is worth noting that *C. crypta* is unique as its mycelium completely colonizes culture plates within a two-week period when cultivated on MEA and PDA, and within a four-week period when cultivated on CMD, MLA, and PCA media at 23 °C compared to *C. melanospora* and *C. sordida*. In addition, *C. crypta* grows well at 37 °C and exhibits a growth also at 41 °C (Fig. 6). The mycelium of *Ceratostomella* spp. *in vitro* is pigmented and remains sterile. In *C. crypta*, we observed monilioid hyphae, either branched or unbranched, growing from the septate hyphae. On MEA and MCA, monilioid hyphae are more dominant compared to those on PDA. Occasionally, these hyphae appear tuberose (budding-like), a feature that becomes more pronounced with age (Fig. 6F).

Ceratostomella crypta is represented by three isolates in our phylogeny. Two strains that were isolated from ascospores originate from the same locality in the Czech Republic, while the third is from the USA and is only known in its asexual state. In the Czech specimens, ascospores were observed either strongly collapsed within the asci (CBS 131683, Fig. 4G–K) or mostly retaining their full shape (CBS 131684, Fig. 4E, F) after rehydration, considerably impacting the ascus size. In the closely related species, such as *C. melanospora* and *C. sordida*, the difference in ascus size is less pronounced based on ascospore shape.

***Ceratostomella cuspidata* (Fr.) Réblová, Mycologia 98: 77. 2006.**

Sphaeria cuspidata Fr., Syst. Mycol. 2: 220. 1823. Basionym.
≡ *Ceratostoma cuspidatum* (Fr.) Sacc., Syll. Fung. 1: 474. 1882.

Description. See Réblová (2006).

Specimens examined. Belgium • Locality and date unknown; B. Declerque (IFBL 57.31, culture no longer viable). New Zealand • West Coast Region, Westland District, Mount Aspiring National Park, Makarora Bush Walk, 500 m N of NP Headquarters in Makarora; decaying wood of *Nothofagus* sp.; 30 Mar 2005; M. Réblová M.R. 2964/NZ 629 (PDD 123700, culture ICMP 17629).

Habitat and geographical distribution. Saprobe on decaying wood of *Nothofagus* sp., *Quercus* sp., and other unidentified hosts, known in the Czech Republic, New Zealand, Norway and Sweden (Fries 1823; Réblová 2006; MyCoPortal). According to GlobalFungi, *C. cuspidata* is distributed in temperate and subtropical regions in both the Northern and Southern Hemispheres. Identical sequences were found in 28 samples isolated from air and soil in forest and anthropogenic habitats, and occasionally in croplands, grasslands, and shrublands biomes in Australia, Indonesia and New Zealand. The environmental data suggest that *C. cuspidata* is especially widespread in Australasia.

Notes. In our phylogeny, the species is represented by two isolates from Belgium and New Zealand. *Ceratostomella cuspidata* is well distinguishable from other species by its suballantoid to reniform ascospores, often flattened on one side, measuring 4–5 × 2–3 µm (Réblová 2006). The ascospores are arranged in a fascicle or they are 2–3-seriate in the sporiferous part of the ascus. *Ceratostomella rostrata* closely resembles *C. cuspidata* but stands out due to its larger ascomata and narrower allantoid to suballantoid ascospores.

Ceratostomella melanospora **Réblová, sp. nov.**
MycoBank No: 855704
Figs 7, 8

Etymology. *Melanos* (Greek) meaning black, dark, *spora* (Latin) from Ancient Greek *sporá*, meaning a seed, referring to brown ascospores.

Type. Czech Republic • Pardubice Region, Chrudim district, Železné hory Mts. Protected Landscape Area, Horní Bradlo, Malá Střítež settlement, Polom National Nature Reserve; 600 m alt.; on decaying wood of *Fagus sylvatica*; 9 Oct 2020; M. Réblová M.R. 4088 (holotype PRA-21822!, ex-type culture CBS 147993).

Description. ***Sexual morph*****.** Ascomata non-stromatic, densely grouped or solitary, superficial, semi-immersed or immersed with only neck protruding. Venter 300–480 µm diam, subglobose, upright or lying horizontally in the host tissue, dark brown to black, with brown, septate, slightly flexuous hairs 2.5–4 µm wide sparsely covering the sides and bottom. Neck 90–100 µm wide, up to 500 µm long, central, cylindrical, upright, glabrous, tapering, apex sulcate; the neck is sometimes slightly wider near the top. Ostiole periphysate. Ascomatal wall fragile to leathery, 55–65 µm thick, two-layered. Outer layer consisting of thick-walled, dark brown, polyhedral cells with opaque walls of textura prismatica, with several cells forming the external crustose layer ca. 8–13 µm thick, cells tend to be more flattened and paler towards the interior. Inner layer consists of several rows of thin-walled, hyaline, flattened cells. Paraphyses abundant, longer than the asci, may become partially disintegrated with age, septate, constricted at the septa, hyaline, (5–)6.5–10.5 µm wide, wider near the base, tapering to 3–4 µm. Asci 63–78 × 6.5–8(–8.5) µm (mean ± SD = 70.8 ± 4.2 × 7.2 ± 0.7 µm), 51–60(–62.5) µm (mean ± SD = 57.0 ± 3.3 µm) long in the sporiferous part; truncate at the apex, cylindrical, with a short tapering stipe, apical annulus non-amyloid, ca. 2.5 µm wide, 1–1.5 µm high, 8-spored. Ascospores (8–)8.5–10.5(–11) × 4–5 µm (mean ± SD = 9.3 ± 0.7 × 4.5 ± 0.3 µm), ellipsoidal, slightly apiculate at both ends, brown, aseptate, smooth, with an

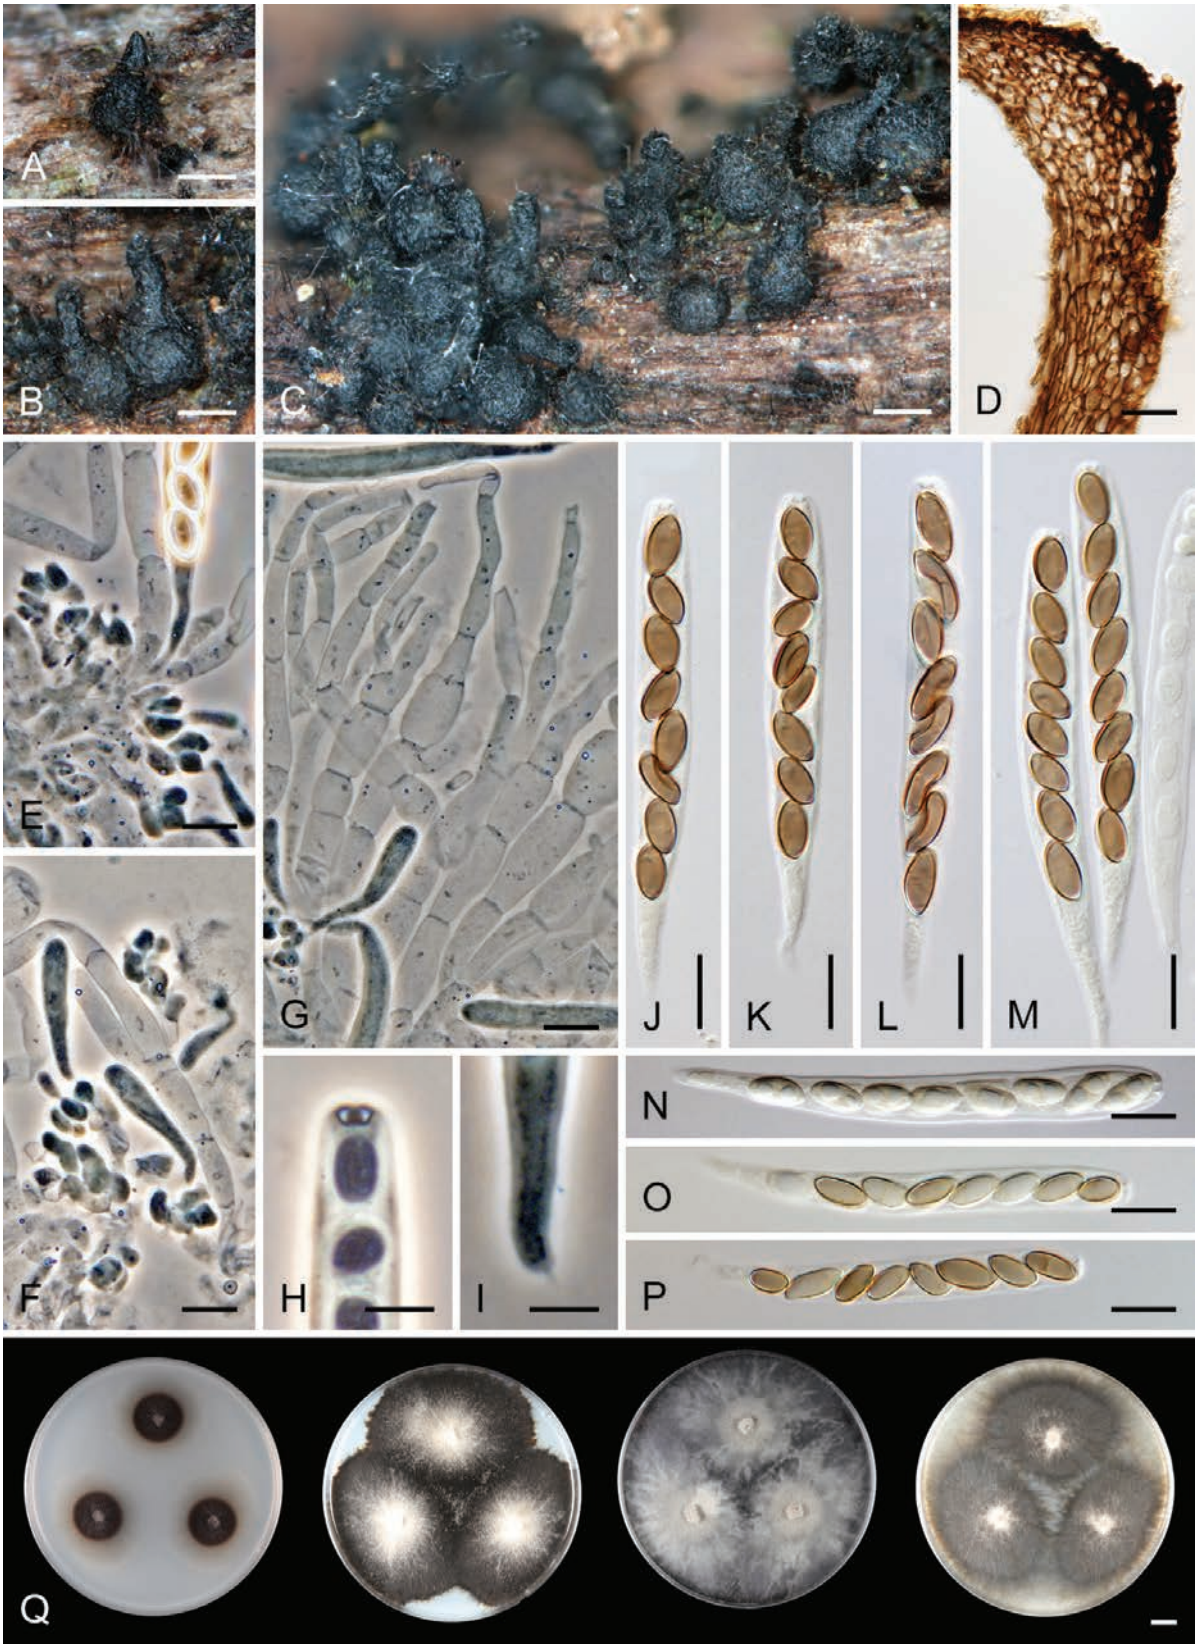

Figure 7. *Ceratostomella melanospora* (**A–P** from holotype PRA-21822 **Q** from ex-type strain CBS 147993) **A–C** ascomata **D** a longitudinal section of the ascomatal wall **E, F** asci with ascogenous cells **G** paraphyses **H** ascal apex **I** stipe of the ascus **J–M** asci with ascospores **N–O** asci of different ages with maturing ascospores **Q** colony morphology at 23 °C after 4 weeks on CMD, MLA, OA and PCA (from left to right). Images: on natural substrate (**A–P**). Scale bars: 500 µm (**A–C**); 20 µm (**D**); 10 µm (**E–G, J–P**); 5 µm (**H, I**); 1 cm (**Q**).

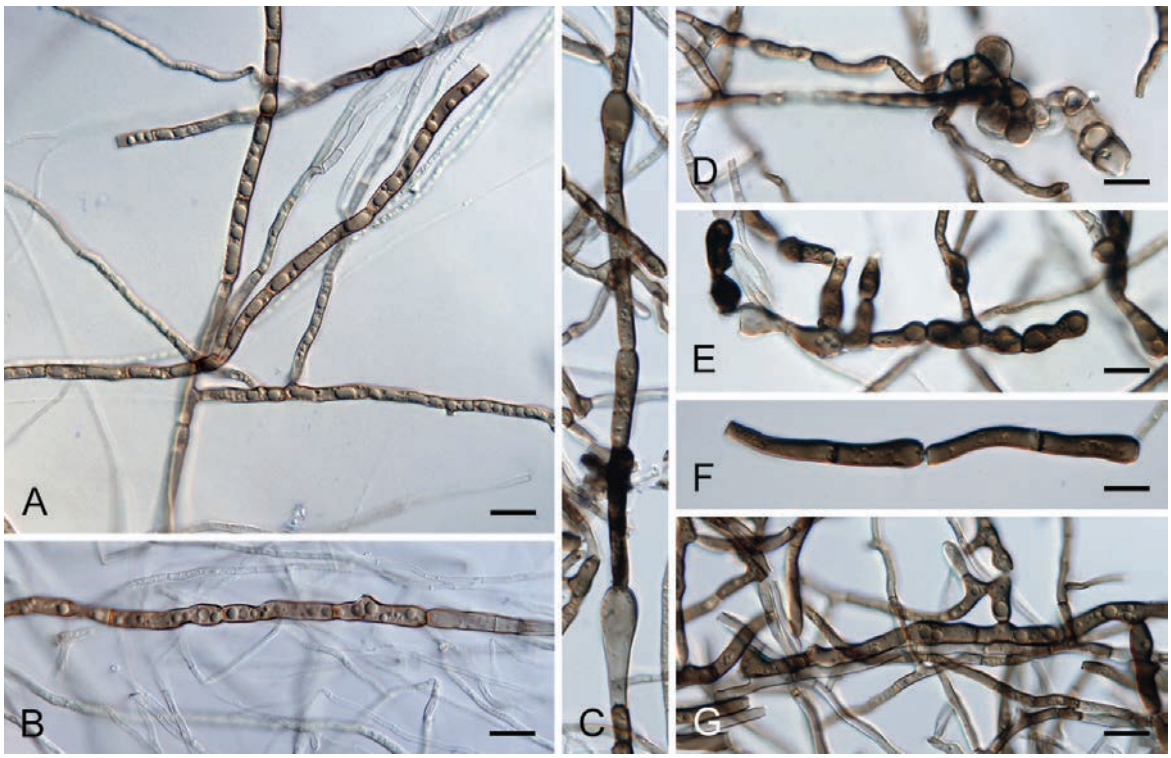

Figure 8. Vegetative mycelium of *Ceratostomella* spp. on MLA **A, B** *C. melanospora* CBS 147993 **C–G** *C. sordida* CBS 116000. Scale bars: 10 µm (**A–G**).

inconspicuous germ pore at one or both ends, occasionally with one oil drop, often collapsing, obliquely uniseriate or partially overlapping, or partially 2-seriate within the ascus. ***Asexual morph*.** Unknown.

Culture characteristics (after 2/4 wk at 23 °C). On CMD colonies 30–32 mm/64–70 mm diam, circular, flat, margin diffuse, cobwebby, mucoid towards the margin, dark brown, with an outer beige zone of conspicuous submerged growth, reverse of the same colour. On MLA colonies 20–21 mm/48–50 mm diam, circular, flat margin fimbriate to somewhat lobate, floccose and whitish grey centrally, cobwebby to mucoid and dark olivaceous grey towards the periphery, reverse of the same colour. On OA colonies 28–30 mm/73–75 mm diam, circular, flat, margin diffuse, lanose and pale olivaceous grey at the centre, sparse to cobwebby and olivaceous black towards the margin, reverse dark brown. On PCA colonies 17–18 mm/53–54 mm diam, circular, flat, margin rhizoidal, submerged, floccose and beige-grey centrally, cobwebby and dark brown towards the margin, reverse dark brown. Sporulation was absent on all media.

Temperature dependent growth at 30, 35, 37, 41 °C was assessed as colony diam on MEA, PDA, and OA, respectively, after a period of two weeks: 30 °C 27–29 mm/23–24 mm/23 mm, 35 °C no growth/no growth/no growth, 37 °C no growth/no growth/no growth, 41 °C no growth/no growth/no growth.

On MLA, colonies are effuse, with submerged hyphae 1–2 µm in diameter. These hyphae are hyaline to subhyaline, sparsely branched, septate, smooth, intertwined with vein-like dark brown hyphae, 3–4.5 µm in diameter. Monilioid hyphae were not observed.

Habitat and geographical distribution. This species is a saprobe on decaying wood of *Fagus sylvatica* and is known to occur in the Czech Republic. According to GlobalFungi, identical sequences were identified in seven environ-

mental samples obtained from various localities within the temperate zone of the Northern Hemisphere. These samples were primarily isolated from air and soil in cropland and forest biomes, with occasional findings in anthropogenic habitats in Canada, China, Italy, and Sweden.

Notes. *Ceratostomella melanospora* is characterised by ellipsoidal, slightly apiculate, mid-brown ascospores arranged 1-seriately, occasionally partially 2-seriately in the ascus. The species is micromorphologically indistinguishable from *C. crypta* and *C. sordida* but differs by the colony characteristics and can also be clearly differentiated by ITS, *rpb2*, and *tef1-α* sequences. Pigmented monilioid hyphae, which formed abundantly in the culture of *C. crypta* and to some extent in *C. sordida*, were not observed in *C. melanospora* (Fig. 8).

***Ceratostomella novae-zelandiae* (Réblová) Réblová, comb. nov.**
MycoBank No: 855705
Fig. 9

Xylomelasma novae-zelandiae Réblová [as '*novaezelandiae*'], Mycologia 98: 87. 2006. Basionym.

Description. See Réblová (2006).

Specimen examined. New Zealand • West Coast Region, Westland District, Haast 300 km SW of Greymouth, Jackson River valley, track to the Lake Ellery; on decaying wood of a stump of *Nothofagus* sp.; 10 Mar 2003; M. Réblová M.R. 2787/NZ 297 (holotype PDD 81433!).

Habitat and geographical distribution. Saprobe occurring on decaying wood of *Nothofagus* sp. in New Zealand (Réblová 2006). According to GlobalFungi, identical sequences were found in two samples isolated from soil in temperate broadleaf forest habitats in New Zealand and Chile.

Notes. *Ceratostomella novae-zelandiae* is distinguished from the other two species in the *C. sordida* complex by its smaller asci, measuring 50–60(–65) × 7–8(–9) µm, and smaller ascospores, measuring 7–8 × (3.5–)4–5 µm.

***Ceratostomella pyrenaica* Réblová & J. Fourn., Mycologia 98: 78. 2006.**

Description. See Réblová (2006).

Specimens examined. Czech Republic • South Moravian Region, Hodonín district, Mikulčice, Skařiny Nature Reserve; on decaying wood of a trunk of *Acer campestre*; 24 Oct 2004; M. Réblová, M.R. 2912 (paratype PRA-21823, CBS 117116); • *Ibid*.; Břeclav district, Valtice, Rendez-vous National Nature Monument; on decaying wood of a branch of *Quercus* sp.; 20 Nov. 2010; M. Réblová M.R. 3566 (PRA-21824, CBS 129343); • *Ibid*.; Břeclav district, Milovice, Křivé jezero Nature Reserve, road near Panenský mlýn; on decaying wood of a trunk of *Quercus* sp.; 17 Nov 2010; M. Réblová M.R. 3584 (PRA-21825).

Habitat and geographical distribution. Saprobe on decaying deciduous wood of *Acer campestre*, *Alnus glutinosa*, *Quercus* sp. and other unidentified hosts, and on decaying basidioma of *Trametes gibbosa*, known from the Czech Republic, Belgium and France (Réblová 2006; MyCoPortal; this study). Accord-

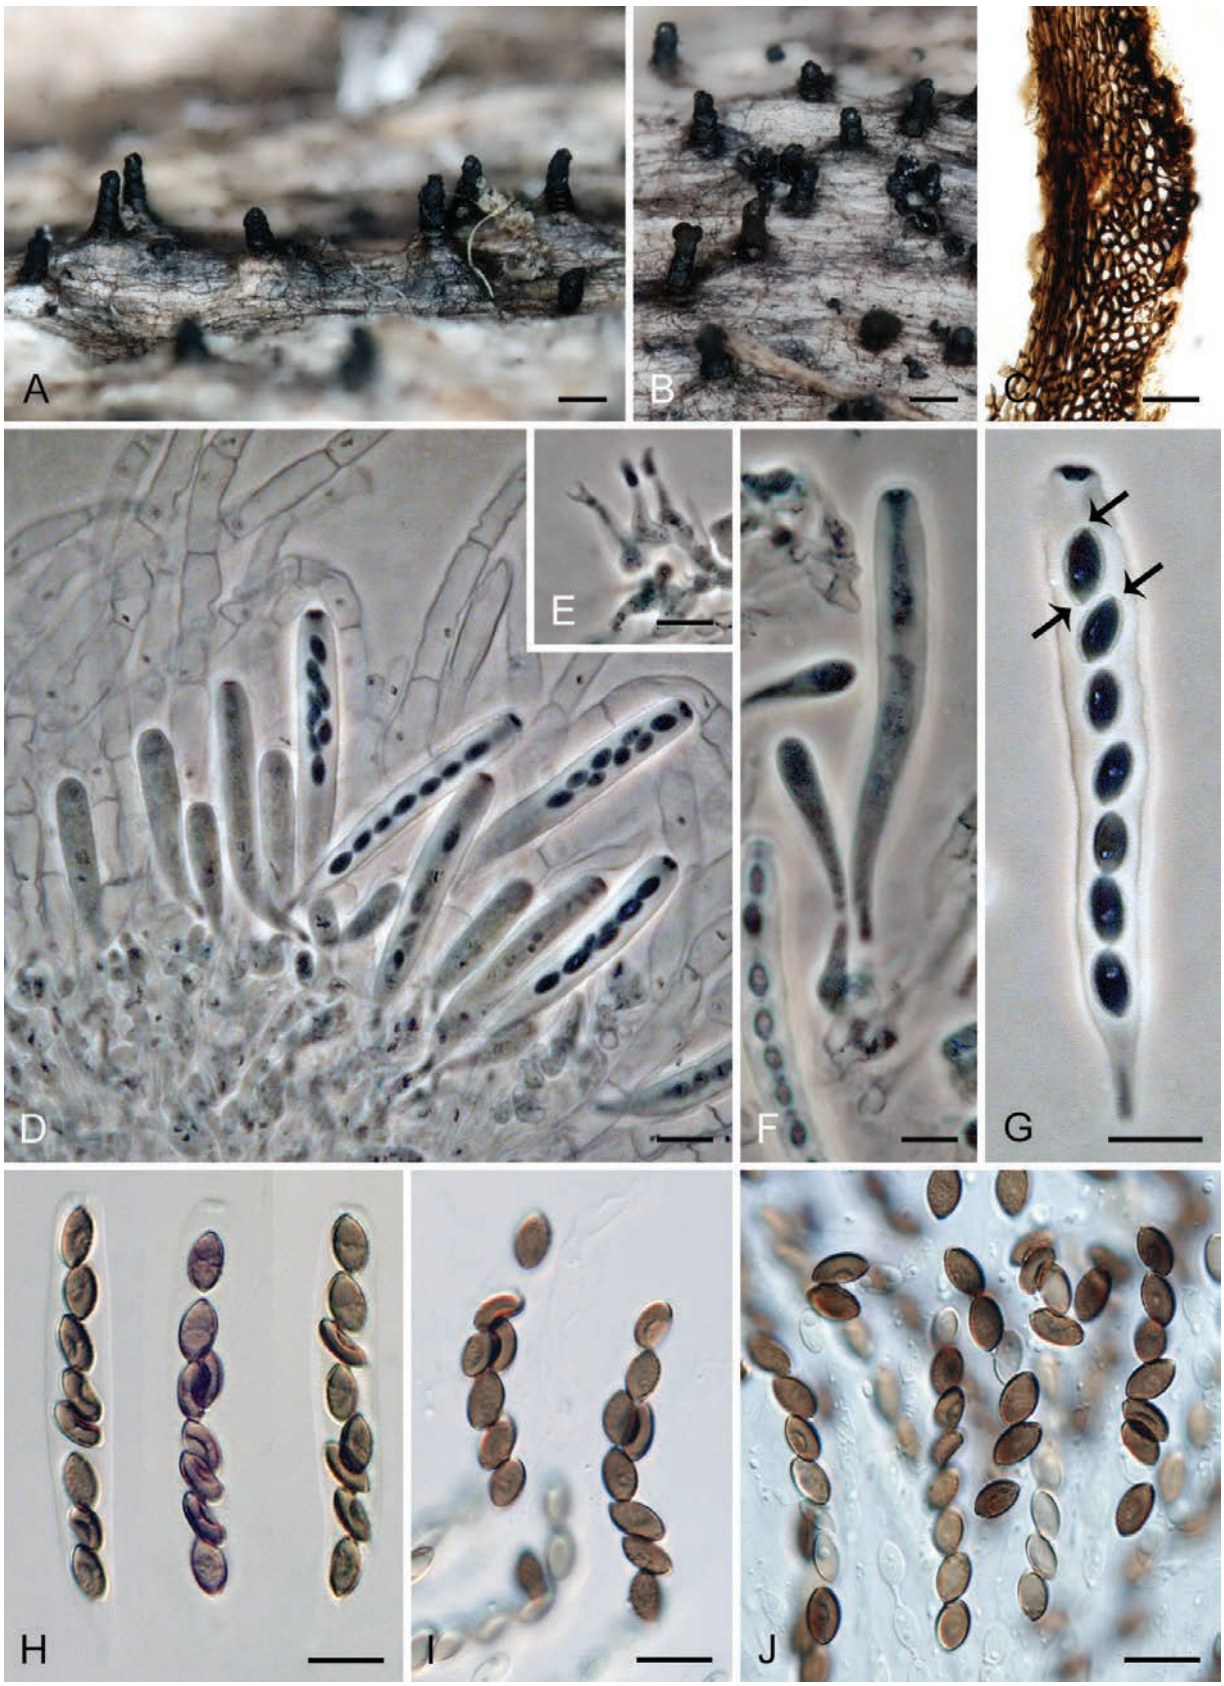

Figure 9. *Ceratostomella novae-zelandiae* (holotype PDD 81433) **A, B** ascomata **C** a longitudinal section of the ascomatal wall **D–F** paraphyses, ascogenous cells, and asci **G** young ascus (arrows indicate ends of ascospores with pores, where the outer wall becomes thinner) **H–J** asci with ascospores. Description. See Réblová (2006).

Specimens examined. France • Pyrénés Atlantiques, Ariège, Rimont, Las Muros; on decaying wood of *Prunus domestica*; 3 Feb 2002; J. Fournier J.F. 02022 (PRA-21826) • *Ibid*.; 21 Apr 2002; J. Fournier J.F. 02070 (PRA-21827).

Habitat and geographical distribution. Saprobe on decaying wood of *Betula papyrifera*, *Prunus domestica*, and on decaying basidioma of *Fomes fomentarius*, known in Canada, France, Italy, and Poland (De Notaris 1867; Réblová 2006; MyCoPortal).

Notes. The neotype of this species (Italy, decaying wood of *Prunus domestica*, P.A. Saccardo, PAD; as *Ceratostoma notarisii*) was designated by Réblová (2006). The species is characterised by ellipsoidal, slightly apiculate ascospores, sometimes flattened on one side, measuring 6–7 × (3.5–)4–5 µm. The ascospores are mid-brown, with a minute pore at each end, and are arranged 1–2-seriately or in a fascicle within the ascus. Given the shape of the ascospores, the species resembles members of the *C. sordida* complex, but it clearly differs by having smaller ascospores.

= *Wegelina polyporina* M.E. Barr, Cryptogamie, Bryol. Lichenol. 19:170. 1998.[1]

Description. See Réblová (2006).

Habitat and geographical distribution. Saprobe on decaying basidioma of *Fomes fomentarius* and decaying wood of *Acer saccharum*, *Acer* sp., *Coriaria* sp., *Fraxinus* sp., *Morus* sp., *Ostrya* sp., *Quercus pedunculata*, *Quercus* sp., *Populus tremuloides*, *Robinia pseudoacacia*, *Ulmus glabra*, *Ulmus* sp., and other unknown hosts, known in Belgium, Canada, Czech Republic, Denmark, Finland, France, Netherlands, Norway, Germany, Poland, Sweden, Switzerland, and the USA (Tode 1791; Kirschstein 1936; Barr 1998; Réblová 2006; MyCoPortal).

Notes. Réblová (2006) designated the lectotype (illustration; Tode 1791: fig. 79) and epitype (Fries´s Scleromyceti Sueciae 116, decayed wood, PRM 666367) of *C. rostrata*. Untereiner (1993), in her revision of the genus *Endoxyla*, cited *Ceratostomella ampullasca* (Saccardo 1882) and *Endoxyla laevirostris* (Munk 1965) as synonyms of *C. rostrata*. However, recent collections and molecular DNA data have revealed that these two species are conspecific and were reclassified as *Natantiella ligneola* (Réblová and Štěpánek 2009). There are numerous records of *C. rostrata* in MyCoPortal; however, these may represent species of *Endoxyla*, as the synonymy of this species was only recently clarified. Accurate identification would require a thorough examination of the herbarium specimens cited, which are housed in various collections around the world.

Ceratostomella rostrata is somewhat similar to *C. cuspidata*; however, it differs in having larger ascomata and pale brown, allantoid to suballantoid, narrower ascospores measuring 4.5–6 × 1.5–2 µm. These ascospores are typically arranged in a fascicle in the upper part of the ascus or are 2–3-seriate within the ascus. Molecular data for this species are not available.

***Ceratostomella sordida* (Réblová) Réblová, comb. nov.**
MycoBank No: 855706
Figs 8, 10

Xylomelasma sordida Réblová, Mycologia 98: 88. 2006. Basionym.

Description. See Réblová (2006).

Characteristics in culture (after 2/4 wk at 23 °C). On CMD colonies 38–40 mm/72–73 mm diam, circular, flat, margin diffuse to slightly fimbriate, cobwebby, olivaceous-brown, reverse of the same colour. On MLA colonies 35–36 mm/76–80 mm diam, circular, flat, sub-entire with a tendency towards a fimbriate edge, lanose, zonate, whitish grey centrally with an olivaceous brown intermediate zone, dark olivaceous grey towards the periphery, reverse dark olivaceous. On OA colonies 34–35 mm/77–79 mm diam, flat, margin diffuse, floccose to cobwebby, olivaceous grey to olivaceous brown, aerial hyphae with

1 Synonymy adopted from Réblová (2006).

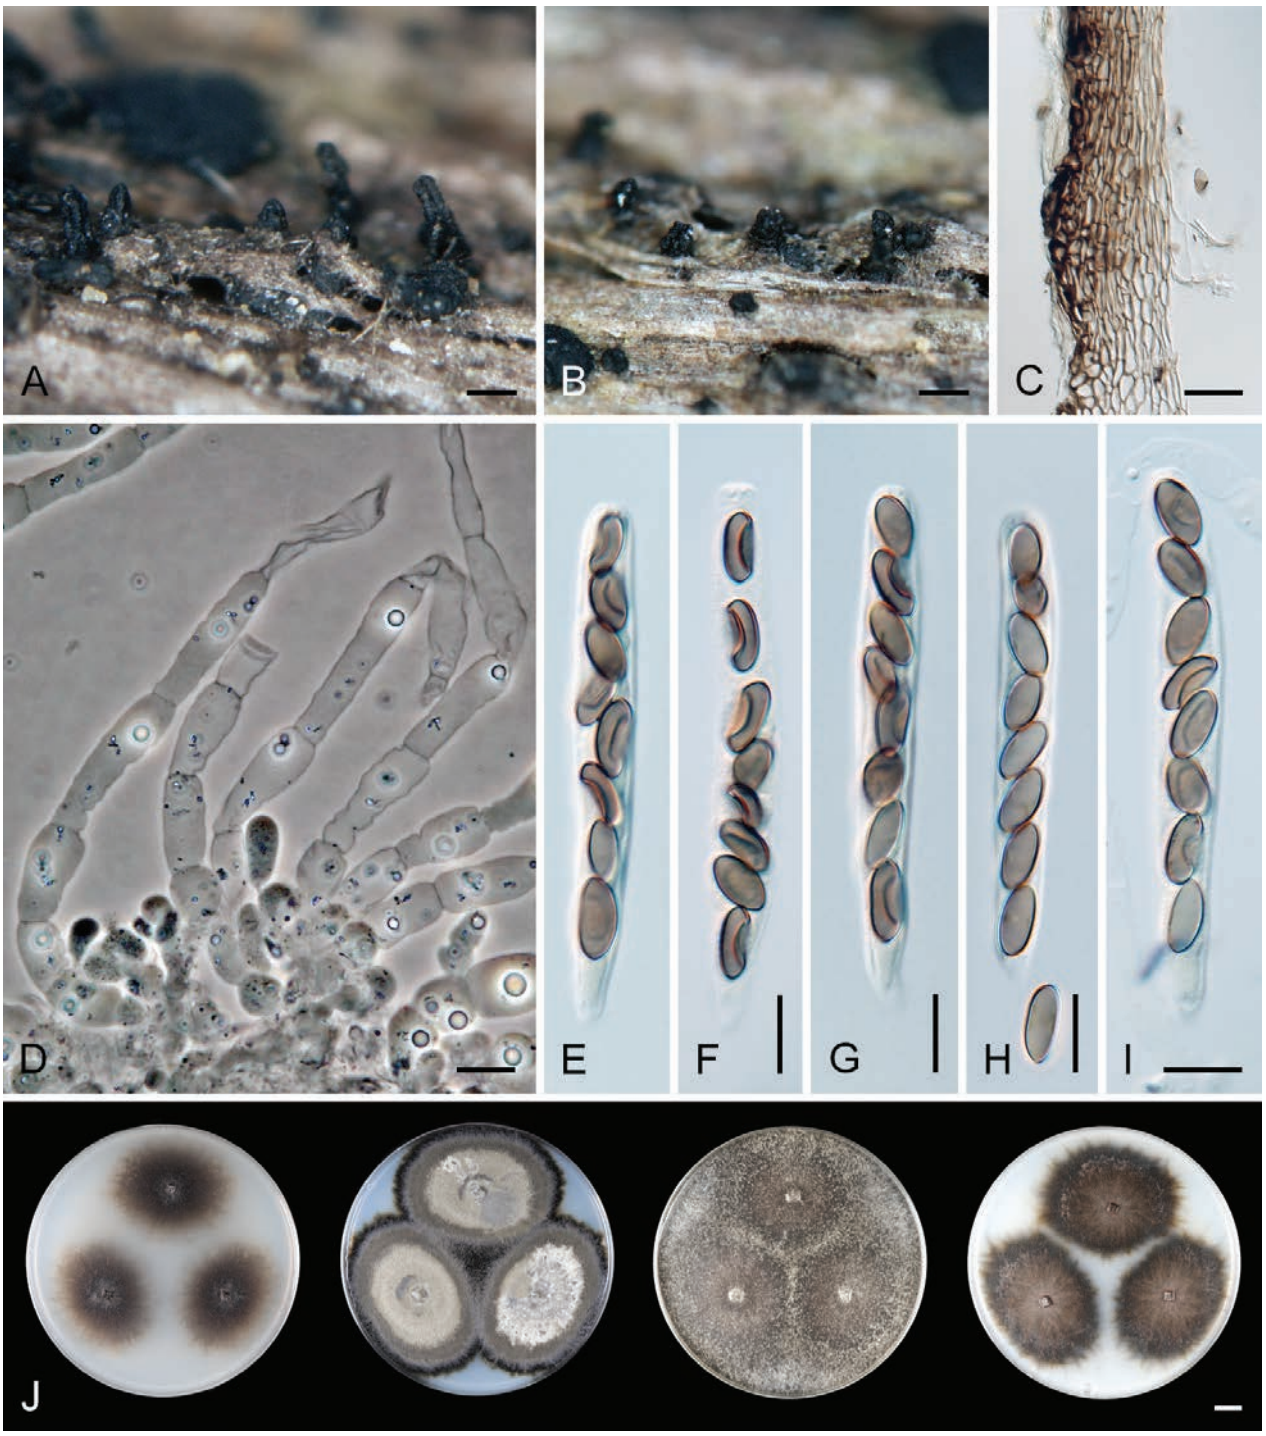

Figure 10. *Ceratostomella sordida* (**A–I** from holotype PRM 902275 **J** from ex-type strain CBS 116000) **A, B** ascomata **C** a longitudinal section of the ascomatal wall **D** paraphyses with ascogenous cells **E–I** asci with ascospores **J** colony morphology at 23 °C after 4 weeks on CMD, MLA, OA and PCA (from left to right). Images: on natural substrate (**A–I**). Scale bars: 500 µm (**A, B**); 20 µm (**C**); 10 µm (**D–I**); 1 cm (**J**).

numerous colourless droplets, reverse of the same colour. On PCA colonies 30–31 mm/58–60 mm diam, circular, flat, margin rhizoidal, sparse to cobwebby, whitish brown at the centre, dark brown towards the periphery, reverse dark brown. Sporulation was absent on all media.

Temperature dependent growth at 30, 35, 37, 41 °C was assessed as colony diam on MEA, PDA, and OA, respectively, after a period of two weeks: 30 °C 58–60

mm/55–58 mm/49–50 mm, 35 °C 60–61 mm/58–59 mm/46–47 mm, 37 °C 37–39 mm/30 mm/14–19 mm, 41 °C germination only/ 5–7 mm/no growth.

On MLA, colonies are effuse, with submerged hyphae 1.5–3 µm in diameter; hyphae are smooth, branched, septate, subhyaline to pale brown, intertwined with dark brown, vein-like hyphae with occasional tuberose formations, 4–6.5 µm in diameter. Dark brown monilioid hyphae 5.5–9 µm in diameter, composed primarily of rectangular cells, occur rarely.

Specimen examined. France • Pyrénés Atlantiques: Ariège, Lescure, Bois du Pas du Baup; 500 m alt.; on rotten wood of *Alnus glutinosa*; 24 Feb 2004; J. Fournier J.F. 04020 (holotype PRM 902275!, ex-type culture CBS 116000).

Habitat and geographical distribution. Saprobe that decomposes the wood of *Alnus glutinosa*, *Eucalyptus viminalis*, *Fagus sylvatica*, *Populus* sp. and other unidentified hosts. It has been found in Argentina, Canada, Czech Republic, Denmark, France, Hungary, New Zealand and Norway (Réblová 2006; MyCoPortal). According to GlobalFungi, *C. sordida* is distributed worldwide in temperate, subtropical and tropical regions of Asia, Australasia, Europe and North and South America. Identical sequences were found in 126 samples isolated mainly in cropland and forest habitats, but also in air, dust, deadwood, grassland, roots, shoots, soil (including rhizosphere soil), tundra, water, and aquatic and anthropogenic habitats in Argentina, Austria, Brazil, Canada, China, Costa Rica, France, French Guyana, Italy, Indonesia, Japan, New Zealand, Papua New Guinea, Romania, Russia, Spain, Sweden, Switzerland, South Korea, and the USA (California, Florida, Iowa, Louisiana, North Carolina, Oklahoma, Pennsylvania, and Tennessee).

Notes. In culture, *C. sordida* rarely forms short monilioid hyphae (Fig. 8), in contrast to *C. crypta*, where these hyphae form frequently and are much longer (Fig. 6). We re-examined the holotype of *C. sordida* (Réblová 2006), focusing on the measurements of both asci and ascospores. Despite fully rehydrating the centrum of the aged material, we observed that the ascospores were slightly smaller 8–10.5 × (3.5–)4–5 µm compared to the previously recorded dimensions of 9–12 × 4–6 µm. Similarly, the asci showed a narrower width of 6.5–8 µm, contrasting with the previously reported range of 7–10(–13) µm. For accuracy, we provide both measurements in the fresh and aged material. Two species introduced in this study, *C. crypta* (CBS 131683, CBS 131684) and *C. melanospora* (CBS 147993), were hidden among the herbarium material labelled as C. *sordida*.

Excluded or ambiguous species

***Xylomelasma moderata* Lar.N. Vassiljeva & S.L. Stephenson, Mycosphere 5: 223. 2014. Nom. inval., Art. F.5.1 (Shenzhen).**

Notes. The species was collected on unidentified decaying wood in the USA (Virginia) (Vassiljeva and Stephenson 2014). However, it was not validly published as an identifier issued by a recognised repository was not cited in the protologue. The species is morphologically distinct from *Ceratostomella* and, based on available morphological data, it represents *Calyptosphaeria subdenudata* (Réblová et al. 2018).

***Xylomelasma shoalensis* A.N. Mill., Y. Marín & Stchigel, Sydowia 68: 224. 2016.**

Specimen examined. USA – Illinois • Montgomery County, Shoal Creek Conservation Area; 39.1871, -89.5963; on 6 cm. diam. decorticated branch on the ground; 4 Apr 2004; A.N. Miller ANM 1 (holotype ILLS 76895!).

Notes. The only available LSU sequence (KX290919, Hernández-Restrepo et al. 2016) of *X. shoalensis* indicates that the species is a member of *Ceratostomella* (Fig. 1). Based on the sequence similarity with *X. sordida* (99.2%), they are likely conspecific. However, according to its diagnosis, this species does not match the generic delimitation of *Ceratostomella*. *Xylomelasma shoalensis* was described with immersed, globose to subglobose and smaller (175–265 µm diam) ascomata featuring a rostrate, slender, non-sulcate neck and hyaline to yellowish-brown, oblong to suballantoid, septate ascospores in unitunicate asci. Its LSU sequence was not obtained from a mycelium of an axenic culture but directly from ascomata on the host. It is evident that morphology belongs to a different genus and species. We examined the holotype, but no traces of a *Ceratostomella*-like fungus could be found. Therefore, due to this ambiguity, *X. shoalensis* is excluded from *Ceratostomella*.

Discussion

Phylogenetic analyses utilising three and five molecular markers, respectively, revealed that *Ceratostomella* (Saccardo 1878) and *Xylomelasma* (Réblová 2006) are congeneric. The analysed species included *C. cuspidata* and *C. pyrenaica* representing *Ceratostomella*, along with the ex-type strains of *X. sordida*, the type of *Xylomelasma*, and *X. novae-zelandiae*. In both phylogenies, *Ceratostomella* consisted of three subclades: *Ceratostomella*, the *C. sordida* species complex, and *C. novae-zelandiae*. However, the position of *C. novae-zelandiae* varied between the two data sets; it either clustered on a basal branch or as a sister to the *Ceratostomella* subclade. *Ceratostomella novae-zelandiae* was originally placed in *Xylomelasma* based on morphological similarities, as no living culture or DNA data were available at the time (Réblová 2006). In this study, DNA was successfully extracted from ascomata of the holotype of *X. novae-zelandiae* PDD 81433 and new ITS, LSU, and SSU sequences were generated. However, the amplification of protein-coding genes was not successful. *Ceratostomella* is currently recognised with eight species which are listed here. Another species, referred to as *Ceratostomella* sp., was placed in the genus by Réblová (2006). It is characterised by its unique globose ascospores, which are distinct from the reported ascospore variability. This species has not been formally described due to the limited herbarium material that could serve as a holotype and lack of a living culture. Recollection and molecular data of this species are needed to support its placement in the genus.

Ceratostomella and *Xylomelasma* exhibit high morphological similarity, with differences primarily in the position of ascospores within the ascus, the variable visibility of the apical annulus, the ornamentation of the neck, and the morphology of the paraphyses. However, the phylogenetic analysis revealed that *Ceratostomella* exhibits greater variability in these morphological traits than previously recognised, supporting the reclassification of *Xylomelasma* as a synonym of *Ceratostomella*. Smaller ascospores, ranging from suballantoid

to reniform shapes, tend to be arranged 2–3-seriately or form fascicles in the sporiferous part of the ascus, whereas ellipsoidal and globose ascospores are generally 1–2-seriate within the ascus. The ascospores are aseptate, glabrous and hyaline when young, becoming brown at maturity before being released from the asci. Characters such as the terminal germination pores are particularly well-visible in immature hyaline ascospores (Fig. 9G). A common characteristic of *Ceratostomella* ascospores is their frequent collapsing apparently upon drying, which may influence the size of the sporiferous part of the ascus.

Species of *Ceratostomella* typically possess a thick ascomatal wall, often adorned with tubercles on the exterior. This wall is composed of thick-walled, dark brown to dark reddish-brown cells, which may contain Munk pores (*C. cuspidata*, *C. rostrata*, and *C. sordida*). The neck in all species is sulcate and ornamented with 4–5 ridges at the top, except for *C. novae-zelandiae*, which has a glabrous neck. The apical, non-amyloid annulus is present in all species and is most visible with phase contrast microscopy, although its visibility can vary. In the former *Xylomelasma* species, *C. sordida* and *C. novae-zelandiae*, the paraphyses are composed of slightly longer cells, but are similarly constricted, primarily in the lower part.

A prominent morphological trait shared by both genera is the ascogenous system. This system comprises short ascogenous hyphae with lateral and terminal discrete cells from which asci emerge as outgrowths. The asci and ascogenous cells are connected by a tapering stipe; its bottom part is sometimes visible as a thread-like connective between the ascus and ascogenous cell. The stipe eventually disintegrates at maturity, allowing the asci to float freely in the centrum. The ascus stipe often contains non-refractive material deposited at the basal part, which becomes visible after the ascus dehisces from the ascogenous cell.

The morphology of the ascogenous system can be peculiar in some taxa and has significant diagnostic value at the genus level. These taxonomically important traits include the attachment of asci to ascogenous hyphae, the presence or absence of discrete cells from which asci arise, and the overall architecture of these formations. For instance, members of the order Calosphaeriales, many of which include former *Ceratostomella* species, (including genera such as *Calosphaeria*, *Flabellascus*, *Jattaea*, *Pleurostoma*, and *Togniniella*) and Togniniales (*Phaeoacremonium*) possess morphologically distinct ascoma centrums specific to each genus (Barr 1985; Barr et al. 1993; Mostert et al. 2006; Réblová 2011; Réblová et al. 2015a).

Another example of a distinct ascogenous apparatus is found in the genus *Barbatosphaeria* of Barbatosphaeriaceae, which encompasses several species initially classified in *Ceratostomella*. This feature was first observed in *B. fagi* by Samuels and Candoussau (1996) and later recognised as a diagnostic feature of the genus by Réblová et al. (2015b). In *Barbatosphaeria*, the asci taper towards a slender stipe, with the basal part of the stipe conspicuously swollen. This swollen base remains attached to the ascogenous hyphae after the mature ascus is liberated and floats freely in the centrum. The attachment of asci to ascogenous hyphae and the mechanism of ascus dehiscence in *Barbatosphaeria* is somewhat similar to that of *Ceratostomella*, its closest relative, although the stipe in *Barbatosphaeria* is more robust and does not transform into a thread-like filament. The ascogenous cells present in *Ceratostomella* are

absent in *Barbatosphaeria*. However, the attached torso of the swollen base of the ascus stipe in *Barbatosphaeria* mimics these cells and may represent an evolutionary pathway, leading to the development of discrete ascogenous cells.

Phylogenetic analyses using three distinct barcodes have uncovered two cryptic species within the *C. sordida* complex, now identified as *C. crypta* and *C. melanospora*. By analysing five genes: the slow-evolving rDNA genes LSU and SSU, alongside a rapidly evolving ITS gene (primary fungal barcode, Schoch et al. 2012) and the slow-evolving protein-coding genes *rpb2* and *tef1-α* (non-rDNA secondary barcodes, Stielow et al. 2015), we were able to elucidate the phylogenetic relationships within the *C. sordida* species complex (Fig. 2). These findings were corroborated by phylogenetic analysis based on the LSU, SSU, and *rpb2* genes (Fig. 1), further validating the distinctiveness of the new species within the complex.

Traditional diagnostic morphological characters have proven insufficient for characterising species within *C. sordida* complex. *Ceratostomella crypta* and *C. melanospora* are morphologically indistinguishable from *C. sordida* and from each other in terms of ascospores, asci, paraphyses, and ascomata, but they can be clearly differentiated by molecular data and the size of their genome. In culture, their vegetative mycelium was darkly pigmented and fast-growing, with all species remaining sterile on various nutrient media and when exposed to UV light. Although no significant morphological differences could be identified among members of the *C. sordida* species complex on the natural substrate, *C. crypta* typically formed monilioid hyphae (Fig. 6) and demonstrated the fastest growth rate *in vitro* (Fig. 5). Notably, within the same time frame, the mycelium of *C. crypta* covered the entire plate (or nearly the entire plate) when grown on MEA, OA and PDA (in two weeks) and CMD, MLA, OA and PCA (in four weeks) compared to *C. melanospora* and *C. sordida*. Interestingly, *C. crypta* and *C. sordida* exhibited growth at 37 °C, which is one of the four key criteria for a fungal strategy to colonize and parasitize the tissues of humans and other mammals (Köhler et al. 2015). Additionally, *C. crypta* demonstrated growth at 41 °C on MEA, OA, and PDA, whereas *C. sordida* exhibited growth at this temperature only on PDA.

The closest relative to *Ceratostomella* recruits from *Barbatosphaeria*. *Ceratostomella* and *Barbatosphaeria* form sister clades; however, their relationship is not statistically supported (–/0.99). This grouping (–/1.0) was first identified in the molecular systematic study of *Barbatosphaeria*, where it received strong support in BI analysis but no statistical support in ML analysis (Réblová et al. 2015b). Zhang et al. (2017) proposed the family Barbatosphaeriaceae to include *Barbatosphaeria*, *Ceratostomella* and *Xylomelasma*), although the grouping was supported only in the BI analysis. The lack of statistical support from ML analysis for this monophyly does not warrant the inclusion of *Ceratostomella* in Barbatosphaeriaceae, as proposed by Zhang et al. (2017). Currently, *Ceratostomella* is accepted as a genus *incertae sedis*, while Barbatosphaeriaceae remains a monotypic family. We suggest that better taxon sampling of species, currently unknown to us, is needed to provide support for the inclusion of *Ceratostomella* in Barbatosphaeriaceae.

Ceratostomella shares several morphological similarities with the genus *Melanospora* (Corda 1837) of the family Ceratostomataceae (*Melanosporales*, *Hypocreomycetidae*), such as ascomata with a rostrate neck (which may

be adorned with coronal setae or lack them) and dull brown, aseptate ascospores with terminal pores. However, *Melanospora* distinctly differs from *Ceratostomella* by its evanescent asci, the absence of paraphyses, and the presence of pseudoparenchyma in the centrum (Luttrell 1951; Cannon and Hawksworth 1982). *Ceratostomella* also exhibits certain similarities to the genus *Cannonia* (Taylor and Hyde 1999), including dark ascomata with long necks and brown ellipsoidal ascospores. Nonetheless, *Cannonia* can be distinguished from *Ceratostomella* by its ascospores with a full-length germ slit, filiform paraphyses, the presence of a rudimentary stroma, and a dark clypeus around the base of the neck. Additionally, *Ceratostomella* differs from both genera in the morphology of its ascogenous system.

Conclusions

This study provides new morphological, molecular, and biogeographical data, offering deeper insights into the genus *Ceratostomella* and clarifying interspecific relationships. Based on phylogenetic analyses and comparative morphological studies, we have transferred the genus *Xylomelasma* to *Ceratostomella*, proposed two new combinations, and described two new species. We recognise eight species within the genus. Members of *Ceratostomella* are distributed worldwide in temperate, subtropical and tropical zones of Asia, Australasia, Europe and North and South America. Based on field observations (Réblová 2006; this study) and metabarcoding data in GlobalFungi (Větrovský et al. 2020), *C. sordida* emerges as the most common species of *Ceratostomella* among those with available DNA sequence data. It was identified in 126 environmental samples and several herbarium collections. On the other hand, *C. novae-zelandiae* is recognised as a rare species. It has been identified in only one field record from New Zealand and two environmental samples from GlobalFungi (Chile and New Zealand), confirming the occurrence of this species in the Southern Hemisphere. To improve the standards and reproducibility of our research, we are publishing WGS data. This not only supports future descriptions of new 'dark taxa' from environmental DNA samples but also facilitates the classification of *Ceratostomella* diversity. By characterising all representatives of the genus through genomic data, future taxonomic efforts will be more streamlined and accurate.

Despite these advances, information on the asexual morph remains lacking, as it did not form in any of the analysed species (Réblová 2006; this study). We advocate the use of dual barcoding, particularly employing ITS primary barcode and secondary barcodes such as *tef1-α* and *rpb2*, to differentiate among members of *Ceratostomella*, especially among morphologically indistinguishable species. Additionally, further research focusing on comprehensive taxon sampling and exploring environmental DNA could enhance our understanding of the diversity and ecological roles of these fungi.

Abstract

Stropharia rugosoannulata is an important edible mushroom in China, but green mold disease has caused significant production and economic losses. In this study, two new pathogens *Trichoderma strophariensis* and *T. viridistromatis* were identified as the causal agents of this disease. During October-November 2023, six strains of the fungal pathogen were isolated from infected fruiting bodies of *S. rugosoannulata* and identified based on morphological characteristics and molecular phylogenetic analyses of internal transcribed spacer (nrITS), the second largest RNA polymerase II subunit (*rpb2*) and the partial translation elongation factor 1-alpha (*tef1-α*) region. The representative isolates of the pathogenic green mold *Trichoderma* species were used to perform a pathogenicity test with spore suspensions, resulting in symptoms similar to those observed in the cultivated field. The same pathogens were successfully re-isolated, thereby fulfilling Koch's postulates. Detailed morphological descriptions, illustrations, culture characteristics, and comparisons with morphologically similar and closely related species are provided.

Introduction

Stropharia rugosoannulata (Wine-cap mushroom), a renowned edible mushroom, also known as Daqiugaigu in Chinese, has been widely cultivated in Poland, Germany, Russia and the United States (Huang et al. 2023). China imported a strain of *S. rugosoannulata* from Poland in the 1980s and began widespread cultivation in the 1990s (Yan et al. 2020). In recent years, *S. rugosoannulata* has been rapidly promoted and widely cultivated throughout China (Gu et al. 2024). With the increasing scale of cultivation, the annual yield of *S. rugosoannulata* in China has exceeded 210,000 tons per year (Huang et al. 2023). However, the emergence of various diseases during the cultivation of *S. rugosoannulata* has driven researchers to in-

tensify their efforts to optimize its growth conditions. Our investigation observed green mold disease on the soil surface and fruiting bodies of *S. rugosoannulata* from three different localities. This disease incidence can lead to mushroom rot and a decline in yield and quality. The dedication of researchers to addressing this issue is a reassuring sign for the future of *S. rugosoannulata* cultivation.

Green mold disease is a major prevalent disease that frequently arises during mushroom development and is characterized by green, villiform mycelia on the surface (Li et al. 2013). *Trichoderma* Pers. (Hypocreales, Ascomycota) is a saprobic fungus found in soil, healthy plants, wood, and other fungi and plays a crucial role as the causative agent of green mold disease. *Trichoderma* species are widely used to combat fungal pathogens (Hasan et al. 2012; Liu et al. 2012; Li et al. 2013; Abo-Elyousr et al. 2014; Poveda et al. 2019), produce antibiotics, enzymes, and biofuel (Degenkolb et al. 2008; Jun et al. 2011; Wijayawardene et al. 2022). Additionally, *Trichoderma* species contribute to the bioremediation of xenobiotic compounds in water and soil (Katayama and Matsumura 1993; Harman et al. 2004; Ezzi and Lynch 2005). Currently, *Trichoderma* comprises more than 500 species globally, based on the literature search (Jaklitsch 2009; Jaklitsch and Voglmayr 2015; Jambhulkar et al. 2024), legitimate names in the Mycobank (https://www.mycobank.org.) and in the Species Fungorum database (www.speciesfungorum.org; accessed on 23 October 2024).

Trichoderma has two types of species with differing ascospore colours, namely hyaline and green ascospores. Chaverri and Samuels (2004) pioneered comprehensive research on green-spored *Trichoderma* species, providing foundational insight into their taxonomy and systematics. Subsequently, Jaklitsch and Voglmayr (2015) proposed a comprehensive classification primarily based on molecular phylogenetic analyses rather than the color of ascospores, dividing them into six subclades: *Ceramicum*, *Chlorosporum*, Harzianum, *Helium*, *Spinulosum*, and *Strictipile*. However, other researchers have not recognized this classification, largely due to the inconsistencies between molecular sequence data and morphological characteristics, as highlighted by Chen and Zhuang (2017). Bustamante et al. (2021) used multi-locus phylogenetic analyses alongside four DNA-based approaches to accurately delimit species within the *Trichoderma* Harzianum lineage, including most green-spored species.

The present study was conducted based on the pathogen of the green mold disease, aiming to characterize and identify the isolates. Six isolates were isolated from soil samples and fruiting bodies of *S. rugosoannulata* cultivated fields in three different regions of Guizhou Province, China. The study described two new species and compared their morphological characteristics among closely related species. A combined dataset of ITS, *rpb2*, and *tef1-α* was used for the thorough phylogenetic analyses, ensuring the reliability of the results.

Materials and methods

Pathogen collection, isolation, and maintenance

Infected fruiting bodies of *S. rugosoannulata* were collected from mushroom-cultivated fields at Baiyun and Shuicheng counties (23°4'23.6352"N, 120°37'39.7812"E and 24°55'39.936"N, 121°11'30.264"E), Guizhou Province,

China in October-November 2023. Field photographs of the fresh specimens were taken with a Canon EOS 1200D (Canon, Japan) or Sony DSC-W830 (Sony, Japan) camera. The specimens were packed in aluminium foil and transferred to the Plant Pathology Laboratory at Guizhou University for isolation. Fungal pathogens on infected fruiting bodies were isolated using the spread plate and tissue isolation method following Wang et al. (2019). Purified cultures were incubated on potato dextrose agar (PDA), malt extract agar (MEA), and synthetic low nutrient agar (SNA) plates at 25, 30, and 35 °C. The holotype specimen was deposited in the Herbarium of the Department of Plant Pathology, Agricultural College, Guizhou University (HGUP). All single ex-type strains were deposited in the Culture Collection of the Guizhou University, China (GUCC) Department of Plant Pathology at Agriculture College and maintained in 25% (v/v) glycerol at −80 °C for long-term preservation (Zeng et al. 2022). Index Fungorum numbers were registered for the new taxa (https://www.indexfungorum.org/names/Names.asp).

Pathogenicity assays

A pathogenicity test was conducted by inoculating fungal mycelial blocks and spore suspensions from six strains isolated from Baiyun, Shuicheng, and Anshun counties onto the soil surface and fruiting bodies of *S. rugosoannulata*, following the updated protocol of Tian et al. (2017). All strains were incubated at 25 °C for 10 days. Control checks (CK) included PDA blocks and distilled water, replacing the mycelial blocks and spore suspensions. Photographs of the inoculated soils were taken after one, seven, and 10 days to monitor the development of any green mycelia. After the 10-day incubation, fungal pathogens were re-examined and re-isolated from the diseased areas to fulfill Koch's postulates, ensuring accurate identification of pathogenicity (Zhang et al. 2015; Xie et al. 2024). The experiment was repeated three times to validate the results and account for variability.

Morphological studies

Micro-morphological observations were performed from culture photographs of fresh stromata, which were taken using an ultra-depth field stereomicroscope (digital microscope system Keyence VHX-7000) to illustrate the macrostructures. Sections were made using a stereomicroscope (Leica DM2500) and mounted in water or a rehydrated 5% KOH solution. The cultures were incubated at 25 °C in darkness (Põldmaa 2011; Wei et al. 2024). Approximately 30 morphological measurements of new species were made for each feature using the ZEN 3.0 (blue edition) (Jena, Germany) software (Zeiss Scope 5 with color camera AxioCam 208) with differential interference contrast (DIC) optics to observe the morphological characteristics (Jaklitsch and Voglmayr 2015; Fu et al. 2024; Zeng et al. 2024). Colony characteristics, i.e., color and texture on PDA (Potato dextrose agar; 200 g potatoes, 20 g dextrose, 20 g agar per L), MEA (malt extract agar; 30 g malt extract, 5 g mycological peptone, 15 g agar per L) and synthetic low nutrient agar (SNA) plates at 25, 30 and 35 °C were observed and noted over 14 days.

Molecular studies

DNA extraction, Polymerase Chain Reaction (PCR) and sequencing

The genomic DNA was extracted from the colony of the isolates cultured at 25 °C, PDA for seven days using a CwBiotech Plant Genomic DNA Kit (Changping, Beijing, China) following the manufacturer's protocol.

The internal transcribed spacer (nrITS), the second largest RNA polymerase II subunit (*rpb2*) and the partial translation elongation factor 1-alpha (*tef1-α*) regions were amplified using the primer pairs ITS5/ITS4, EF1-728F/TEF1LLErev, and fRPB2-5F/fRPB2-7cR, respectively (White et al. 1990; Carbone and Kohn 1999; Liu et al. 1999; Jaklitsch et al. 2005). A 25 mL reaction mixture containing 1.6 mL dNTP mix (2.5 mM/mL), 0.2 mL Taq polymerase (5 U/mL), 2 mL polymerase buffer (10 /mL), 1 ml forward and reverse primers (10 mM/mL), and 1 mL DNA template was used for PCR experiments. Amplifications were carried out in a T100™ Thermal Cycler (BIO-RAD), which was configured for an initial denaturation at 95 °C for 3 minutes, followed by 34 cycles of 1 minute at 95 °C, 30 seconds at 55 °C, 1-minute extension at 72 °C, and a final extension at 72 °C for 10 minutes. Sangon Biotech (Shanghai) Co., Ltd. sequenced PCR products using the same PCR primers used in amplification operations. The newly generated sequences were checked with BioEdit v.7.2.5 (Hall 1999) and deposited in the NCBI GenBank nucleotide database for future reference.

The amplified sequences were subjected to BLASTn searches in the GenBank nucleotide database for comparison. Subsequently, closely related sequences of the taxa exhibiting zero E-values were retrieved from the database to generate the dataset. Besides, the sequences used by earlier studies on *Trichoderma* (Zeng et al. 2022) were also obtained from the database to prepare the final dataset (Table 1).

Dataset representation

Sequences of the closely related taxa with zero E-value were searched from the BLASTn analyses in the NCBI GenBank nucleotide database. A preliminary BLAST search with the newly amplified sequences of the collected specimens showed the highest sequence similarity with the members of the *Trichoderma* Pers. Hence, a dataset was prepared based on the highest-scored hits of the BLAST search plus the datasets used in the earlier studies on *Trichoderma* (Zeng et al. 2022).

Sequence alignment and phylogenetic analyses

The newly generated reverse and forward sequences were reassembled manually using BioEdit version 7.0.5.3 (Hall 1999) and were aligned with MAFFT v.7.427 (Katoh et al. 2019) in an online platform (https://www.ebi.ac.uk/Tools/msa/mafft/). The aligned sequences were imported to MEGA v.7.0 (Kumar et al. 2016) for manual improvement and trimming of both ends.

A quick phylogenetic analyses of DNA fragments (ITS, *rpb2* and *tef1-α*) from 128 strains were performed with alignments and associated data matrices, including six isolates in this study (GUCC TB1117, GUCC TB1118, GUCC TB1119, GUCC TB1120, GUCC TB1121 and GUCC TB1122) and 122 reference strains (Table 1) by using offline software 'One-click Fungal Phylogenetic Tool'

(OFPT-https://ofpt.guhongxin.com) following its default protocol (Zeng et al. 2023). The final Maximum likelihood analysis was performed with RAxML-HPC2 v. 8.2.12 (Stamatakis 2014) on the CIPRES Science Gateway platform using the GTR+I+G model with 1,000 bootstrap replicates and Bayesian analyses were conducted with MrBayes v.3.2.2 (Ronquist et al. 2012) using MCMC methods (Geyer 1991) under a GTR+I+G model. Markov chains were run for 2 × 106 generations, saving a tree every 100th generation with all the remaining parameters set to default. Bayesian analyses reached a standard deviation of split frequency of 0.0048 at the end of the specified number of generations. For both analyses, the initial 25% of trees recovered (10,000 trees) were excluded as the burn-in, while the remaining 30,002 trees were utilized to estimate the posterior probabilities for the group. ML bootstrap values (MLBS) ≥ 70% and Bayesian posterior probabilities (PP) values ≥ 0.95 are displayed in the phylogenetic tree. The resulting trees were visualized in FigTree v1.4.3 (Rambaut 2016).

Results

Pathogenicity tests

Both soil inoculating groups of covering mycelial blocks and soil mixed with spore suspension of isolates GUCC TB1117 and GUCC TB1120 exhibited similar symptoms of green mold disease in the field after seven days (Fig. 1g), while

Figure 1. Scale bars: 20 mm (**a–e**); 10 mm (**f**); 20 mm (**g**); 10 mm (**h**); 20 mm (**l, j**); 10 mm (**k, l**).

the control group did not have (Fig. 1d). The green mycelia can be observed on the surface of the mushroom tray after 3–5 days and spread fast, covering the whole surface of the substrate and turning green within 10 days (Fig. 1e, f).

The rate of isolates GUCC TB1117 and GUCC TB1120 infecting mushroom tray is about 50%, similar to its incidence in the field. The same fungal pathogen had been observed and re-isolated from these symptoms, which fulfills Koch's postulates (Fig. 1).

Phylogenetic analyses

The phylogenetic analyses were conducted using a combined dataset of nrITS, *rpb2*, and *tef1-α* sequences. A total of 128 sequences were aligned, and this resulted in a dataset consisting of 2934 nucleotides; after the ends of the individual alignments were trimmed, the size of the aligned dataset was as nrITS 610 bp, *rpb2* was 1080 bp, and *tef1-α* was 1244 bp respectively. The best-fit substitution model of each gene is ITS (TIM2+F+R4), *rpb2* (TIM3e+I+G4) and *tef1-α* (TIM+F+R4). The RAxML analysis of the combined dataset yielded a best-scoring tree with a final ML optimization likelihood value of –37957.575772. Estimated base frequencies are as follows: A = 0.233134, C = 0.285526, G = 0.253003, and T = 0.228336; substitution rates AC = 1.134637, AG = 4.477934, AT = 1.149518, CG = 1.048786, CT = 6.335323, and GT = 1.000000; proportion of invariable sites I = 0.544721; and gamma distribution shape parameter a = 0.951765. The Bayesian analysis ran 29,64000 generations before the average standard deviation for split frequencies reached 0.00998. The analysis generated 59,282 trees, from which 44,462 were sampled after burn-in, and the 99% credible set contains 35,309 trees. Our new strains belong to a distinct clade that is genetically distant from *T. britannicum*, *T. aerugineum*, *T. danicum*, and *T. spinulosum* and is divided into four subclades represented by our newly generated strains (Fig. 2). DNA base pair differences also supported the phylogenetic placements of these novel taxa (Table 2).

Table 2. The DNA base differences of our isolates and related taxa in different loci.

Figure 2. A phylogram was constructed using ML analysis, utilizing a combined ITS, *rpb2*, and *tef1-α* sequences dataset. The green-spored *T. longibrachiatum* (CBS81668) was used as the outgroup taxon following Zeng et al. (2022). The tree with the highest score according to RAxML, with a final probability value of *-lnL* = 37957.575772, is displayed. Maximum Likelihood (ML) values equal to or greater than 70% and Bayesian Inference (BI) values equal to or greater than 0.90 are given above the nodes (ML values on the left side of '/' in regular font and BI values on right side of '/' in italics). Type strain sequences are indicated in red bold, while newly generated sequences are shown in black bold. Strain numbers for the sequences are shown in the tree following the taxon name. 'T' denotes ex-holotype strains.

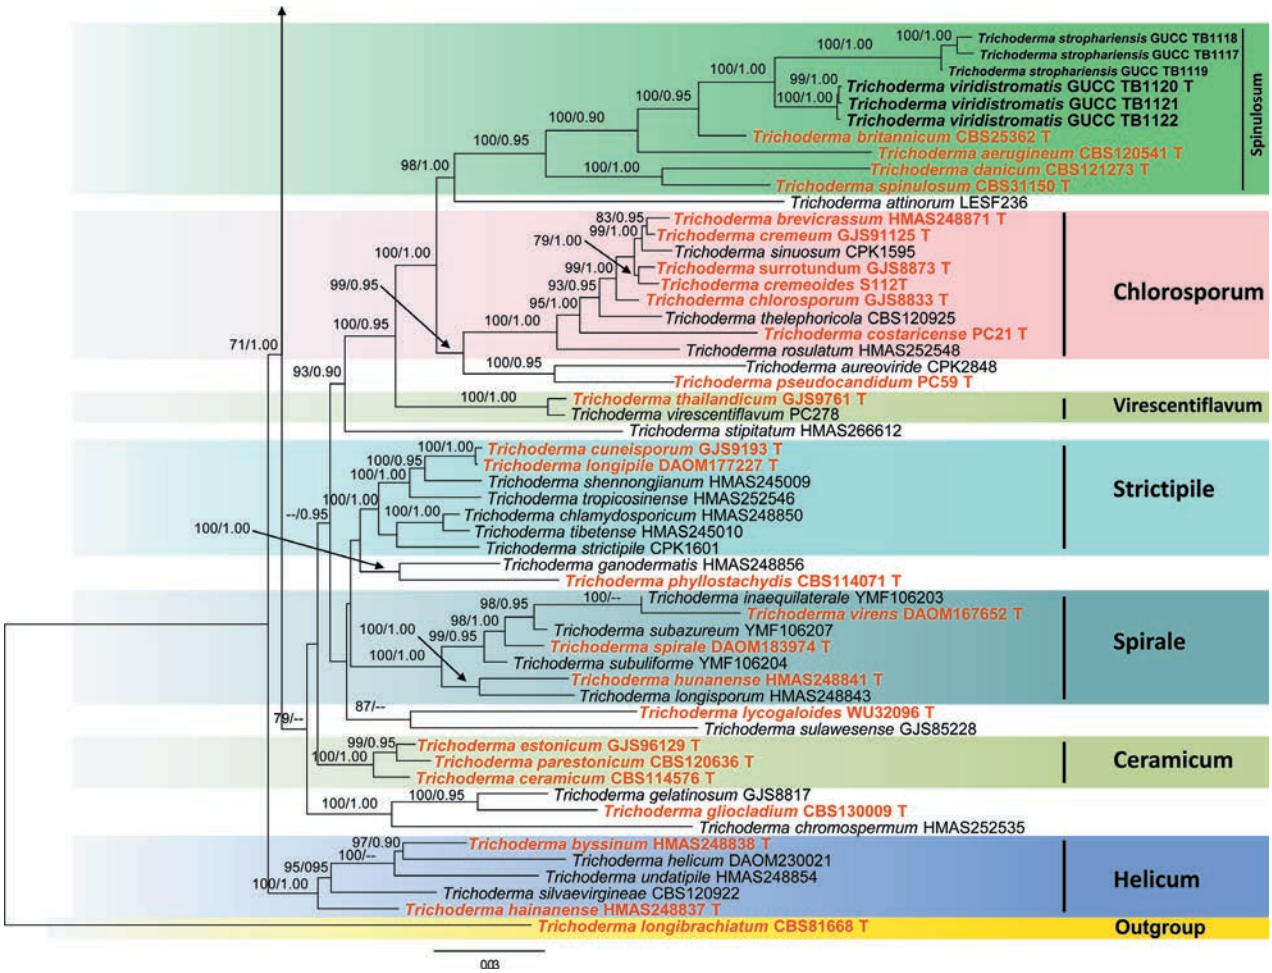

Figure 2. Continued.

Taxonomy

***Trichoderma stropharienses* E. Tarafder & F.H. Tian, sp. nov.**
Fungal Names: FN 902311
Figs 3, 4

Diagnosis. *Trichoderma stropharienses* differs from *T. britannicum* by smaller stromata (0.9–2.2 × 0.8–2 mm) with dark green surface, margin free; surface finely rugose or tubercular, brownish between black ascomata; ostiolar dots absent, inconspicuous or convex to distinctly papillate measuring (27–)35–64(–90) mm diam. Additionally, it is easily distinguished from *T. viridistromatis* by its relatively larger ascospores (8.4–16.9 × 5.5–8.1 µm) and conidia (8.5–25.5 × 5.7–17.9 µm). Phylogenetically, *T. stropharienses* forms a distinct clade and is closely related to *T. viridistromatis*, *T. britannicum*, and *T. aerugineum* with 100% ML and 0.90 BYPP statistical support (Fig. 1).

Holotype. HGUP 24-0001.

Etymology. The specific epithet '*stropharienses*' refers to the occurrence of the new taxon in cultivated mushrooms *Stropharia rugosoannulata*.

Description. *Stromata*, when fresh 1–14 mm in diameter, 1–11 mm thick (n = 10), solitary to sometimes aggregated, discoid or undulate, with brownish margin and pale red, depressed center when young, becoming reddish with ru-

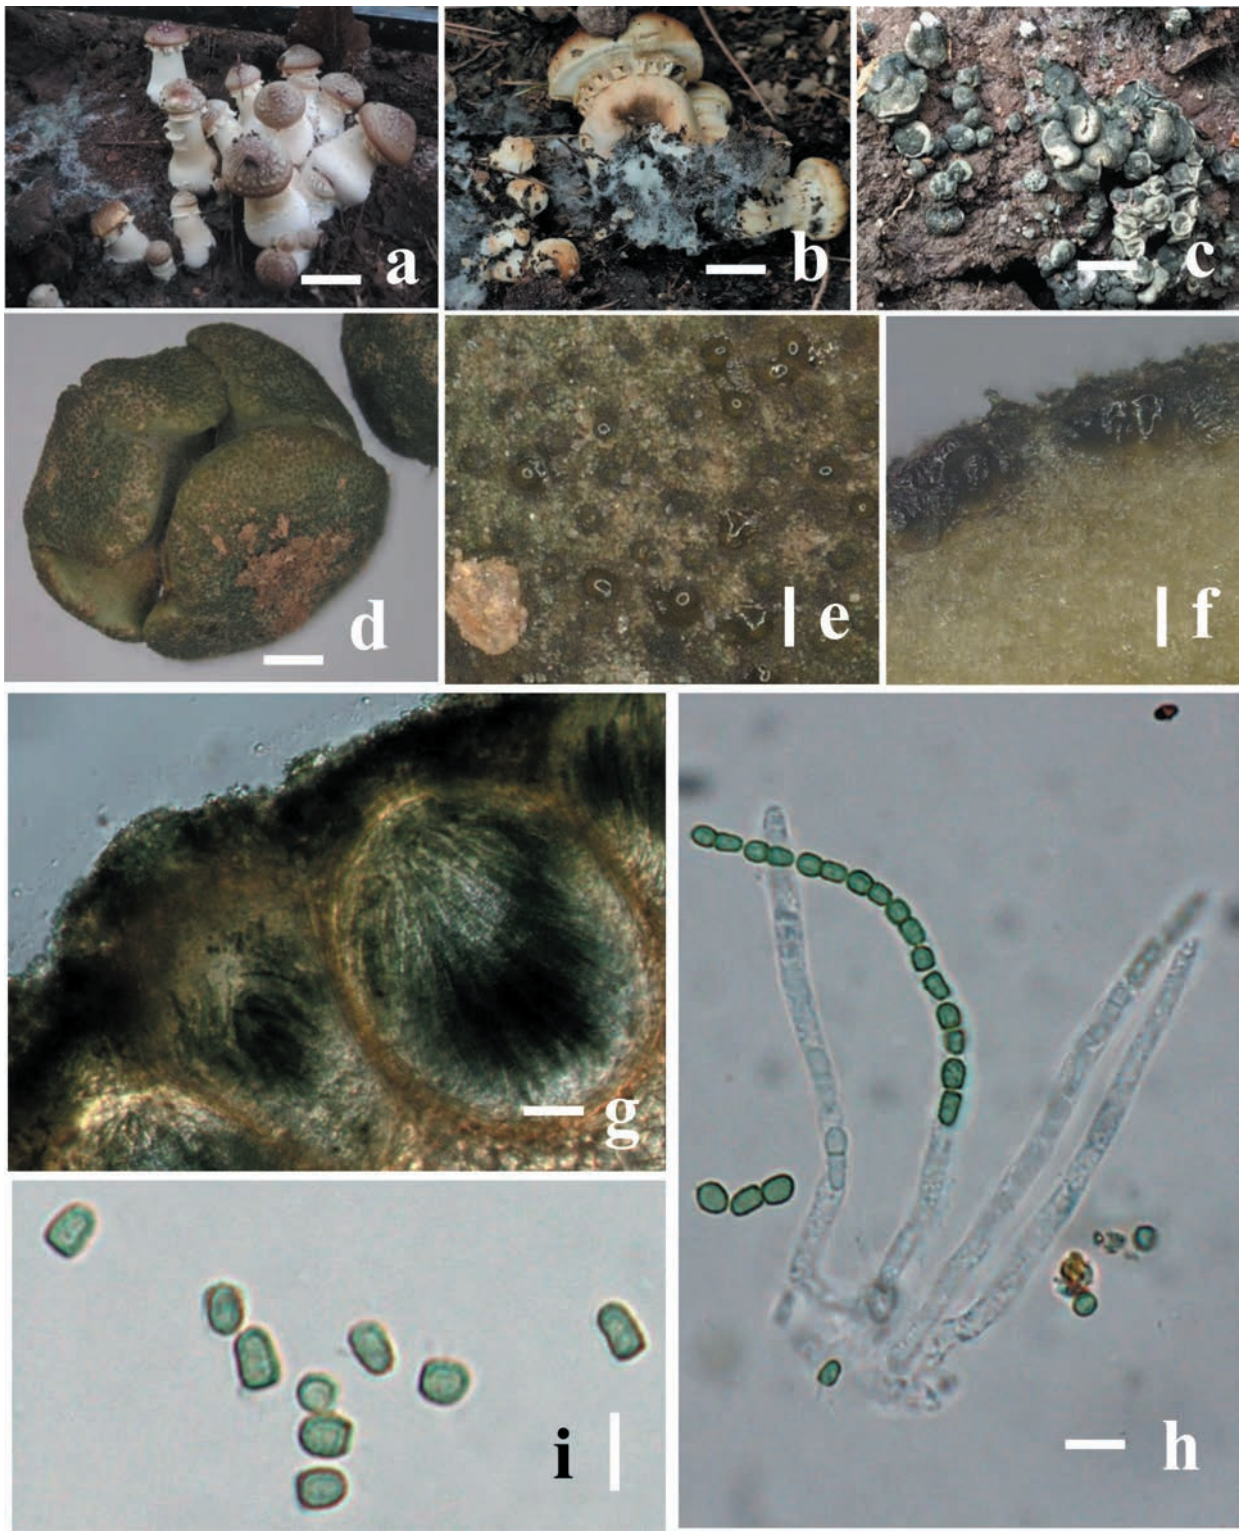

Figure 3. Morphology of *Trichoderma strophariensis* (HGUP 24-0001, GUCC 24-0002) **a, b** disease in the field habitat **c** fresh stromata on natural habitat **d** dry stromata **e** ostiolar dots on stromata surface **f** cortical and subcortical tissues in section **g** ascomatal tissue in section **h** asci with ascospores **i** ascospores. Scale bars: 10 mm (**a, b**); 20 mm (**c**); 100 mm (**d–f**); 50 µm (**g**); 20 µm (**h, i**).

gose surface when mature. Attached to the host by hyphae, easily detached; sides often attenuated downward, surrounded at the base by white cottony mycelium when young. Surface finely rugose, tubercular, brownish between black

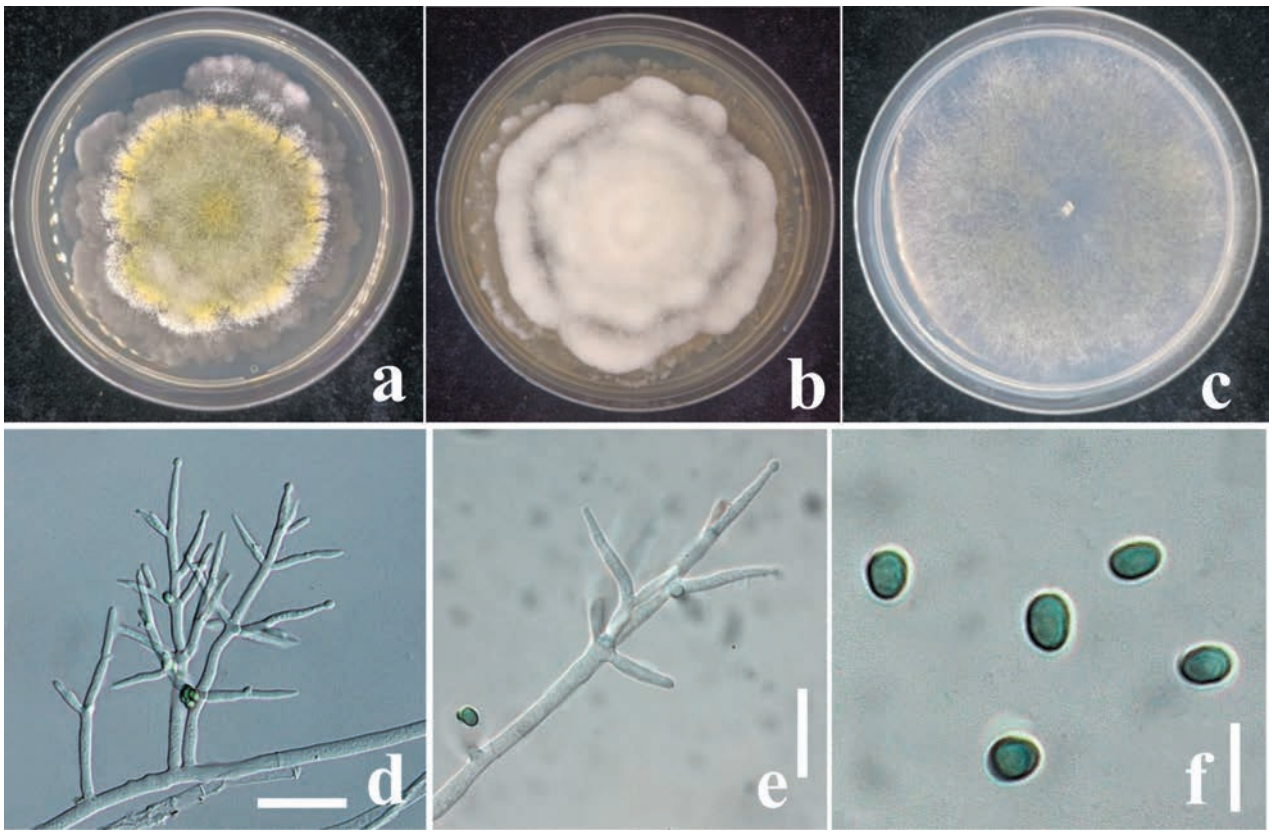

Figure 4. a cultures on MEA (five days) **b** cultures on PDA (five days) **c** cultures on SNA (4 days) **d** conidiophores **e** phialides **f** conidia. Scale bars: 10 µm (**d, e**); 5 µm (**f**).

ascomata; Ostiolar dots are convex to umbilicate, greenish, overall colors light green, darker green when dry, surface and spores green when mature. ***Ostiole*** 14–21 µm wide at apex, 41–59 µm high (n = 30). ***Ascomata*** (139–)175–295(–347) × (113–)151–248(–290) µm (n = 20), flask-shaped or sub-globose, crowded. ***Peridium*** 18–28 µm thick at the base and sides (n = 40), light brown. ***Asci*** (67–)110–146(–207) × (3.7–)5.8–7.7(–9.4) µm, stipe (3–)7–11(–18) µm long (n = 50), containing 16-ascospores, apex slightly thickened, hyaline, cylindrical. ***Ascospores*** (8.4–)9.2–11.6(–16.9) × (5.5–)6.6–7.8(–8.1) µm, l/w (1.2–)1.4–1.6(–2.1) (n = 90), green, verruculose; sub-globose, oblong, elongated, thick-walled.

Culture characteristics. Optimal growth at 25 °C on all media, poor and limited growth at 30 °C, no growth at 35 °C.

On MEA and PDA growth is slow, colony creamy white, finely farinose by scant effuse conidiation; on PDA reverse brownish, surface turning greenish-brown. On MEA at 25 °C after five days colony radius 5–7 mm; colony circular, dense, thick, first whitish, becoming zonate after a few weeks, turning olive-green to brown with yellow greenish, farinose center; conidiation effuse, on short odd verticillium like conidiophores. On SNA colony radius at 25 °C after 2 weeks 6–9 mm; colony dense, hyaline, turning greenish or olivaceous from conidia. Conidiation following growth, effuse, on aerial hyphae and short odd verticillium-like conidiophores, spreading from the plug. ***Conidiophores*** simple, 1–4 level are branched and tapered at the tips, bearing few asymmetric side branches, terminated by solitary phialides of 2–3 divergent phialides. ***Phialides*** (10.5–)37–44(–55) × (1.5–)2.5–11(–12.5) µm (n = 50), mostly gregarious,

cylindrical, less commonly subfusiform, often thickest near the base. ***Conidia*** (8.5–)12.5–16.4(–25.5) × (5.7–)6.5–10.7(–17.9) µm (n = 70), one-celled, variable shape and size, typically oblong and pale olive green when fully mature, sub-globose, oval or ellipsoid and hyaline when immature, straight or slightly curved, sides sometimes pinched, smooth; base often truncate, thick-walled.

Habitat. On mushroom cultivated field, associated with *Stropharia rugosoannulata*.

Distribution. China, Guizhou Province, Guiyang City, and Liupanshui City; Guizhou City in Anshun Province.

Material examined. China • Guizhou, Liupanshui City, Shuicheng District, 2°55'39.36"N, 120°11'30.64"E, on soil surfaces of *Stropharia rugosoannulata* cultivated field, 16-November-2023, E. Tarafder and F.H. Tian (HGUP 24-0001, holotype); ex-type living cultures GUCC TB1117, GUCC TB1118 and GUCC TB1119.

GenBank accession numbers. GUCC TB1117 (ITS: PP920011; *rpb2*: PP954941; *tef1-α*: PP954947); GUCC TB1118 (ITS: PP920012; *rpb2*: PP954942; *tef1-α*: PP954948); GUCC TB1119 (ITS: PP920013; *rpb2*: PP954943; *tef1-α*: PP954949).

Notes. Morphologically, our new isolates are most similar to *T. danicum* in the size of stromata (5–20 mm) but can be distinguished by its generally smaller ascospores and conidia (Table 3); the presence of deeper color of stromata and ascospores, less pigment on media, and faster growth rate on PDA and SNA. However, our new isolates differ from *T. britannicum* by smaller stromata (0.9–2.2 mm) with dark green surfaces (Jaklitsch, 2009). In addition, it differs from other new species (*T. viridistromatis*) in producing cylindrical, less commonly subfusiform phialides (10.5–55 × 1.5–12.5 µm) and larger conidia (8.5–25.5 × 5.7–17.9 µm), typically oblong, subglobose, oval, sometimes ellipsoid and pale olive green after maturity. Phylogenetically, our isolate (HGUP 24-0001) forms an independent clade and clustering with *Trichoderma britannicum*, *T. aerugineum*, *T. danicum*, *T. viridistromatis*, and *T. spinulosum* within the Spinulosum lineage with 100% ML and 1.00 BYPP statistical support (Fig. 2). It exhibits 4% sequence differences (28/610 nucleotides, four gaps) in the ITS region, 4% differences (48/1080 nucleotides, no gaps) in the *rpb2* gene, and 5% differences (64/1244 nucleotides, twenty-five gaps) in *tef1-α* gene when compared with *T. britannicum*. Additionally, the differences between our isolate with *T. viridistromatis* are 4% (29/610 nucleotides, four gaps) in the ITS region, 4%

Table 3. Morphological comparison of *Trichoderma britannicum*, *T. aerugineum*, *T. strophariensis*, *T. danicum*, *T. viridistromatis*, and *T. spinulosum*.

Taxon (holotype)	Ascospores	Conidia	Substratum	References
T. britannicum	10–16 × 4.5–6.2 µm	4.7–19.3 × 4–6.2 µm	Decaying wood of broadleaf trees	Jaklitsch et al. 2014
T. aerugineum	8–12 × 4–6 µm	3–5 × 2–4 µm	Decaying wood	Chaverri and Samuels (2004)
T. strophariensis	**8.4–16.9 × 5.5–8.1 µm**	**8.5–25.5 × 5.7–17.9 µm**	**mushroom species (*Stropharia*)**	**This study**
T. danicum	3–5 × 2.5–4.4 µm	3–3.5 × 2.7–3 µm	On pine wood	Jaklitsch 2009
T. viridistromatis	3.4–5.6 × 2.4–3.3 µm	2.8–4 × 1.7–3.2 µm	mushroom species (*Stropharia*)	This study
T. spinulosum	5–7 × 3–4 µm	3.5–4.7 × 3–3.7 µm	On stems of *Chelidonium majus*	Jaklitsch and Voglmayr 2015

(46/1080 nucleotides, no gaps) differences in the *rpb2* gene, and 5% (65/1244 nucleotides, twenty-five gaps) differences in the *tef1-α* gene. In contrast, the differences in our isolate with *T. danicum* are more than 4% (25/610 nucleotides, eight gaps) in the ITS region, 9% (99/1080 nucleotides, no gaps) in *rpb2* gene, and 8% (105/1244 nucleotides, three gaps) in *tef1-α* gene (Table 2). Therefore, based on both morphological and phylogenetic distinctions, *T. stropharіensis* is introduced as a new species from cultivated mushrooms.

Trichoderma viridistromatis **E. Tarafder & F.H. Tian, sp. nov.**
Fungal Names: FN 902312
Figs 5, 6

Diagnosis. *Trichoderma viridistromatis* differs from *T. aerugineum* by its smaller stromata (0.5–2 mm diam, to ca. 1 mm thick in *T. aerugineum*) and bigger phialides measuring 7–23 × 2.4–4 µm in *T. aerugineum*. In addition, it is easily distinguished from *T. stropharіensis* by its smaller ascospores (3.4–5.6 × 2.4–3.3 µm) and conidia (2.8–4 × 1.7–3.2 µm). Phylogenetically, *T. viridistromatis* forms a distinct clade and is closely related to *T. stropharіensis*, *T. britannicum*, and *T. aerugineum* with 100% ML and 0.90 BYPP statistical support (Fig. 1).

Holotype. HGUP 24-0004.

Etymology. The epithet "*viridistromatis*" refers to an entirely green-colored stroma.

Description. ***Stromata***, when fresh 1–7 mm in diam., 0.5–2 mm thick (n = 10), mostly gregarious, aggregated, discoid or undulate, becoming pulvinate, compact; outline circular to oblong; margin attached or free, surface smooth when immature without ostiolar dots, with yellowish margin and pale red, depressed center when young, becoming reddish with rugose surface when mature. Outline circular, oblong or irregularly lobed. Surface smooth, tubercular or rugose, when young finely velvety. Ostiolar dots absent, ostiolar openings sometimes visible, (16–)20–30(–32) µm (n = 30) wide, inconspicuous, pale, more distinct and shinier after rehydration. ***Ostioles*** (18–)24–30(–45) µm long, plane with the surface, (8–)12–19(–23) µm wide at the apex (n = 30). ***Ascomata*** (69–)75–85(–96) × (36–)41–55(–60) µm (n = 30), numerous, 5–7 per mm stroma length, sub-globose or flask-shaped. ***Peridium*** (7–)11–19(–22) µm (n = 60) thick at the base and sides; hyaline to pale yellowish. ***Asci*** (63–)74–81(–85) × (3.2–)4.2–5(–5.5) µm, stipe (4–)5–11(–14) µm (n = 30) long, containing 16-ascospores, apex not thickened, hyaline, cylindrical. ***Ascospores*** (3.4–)3.6–4.3(–5.6) × (2.4–)2.8–3.1(–3.3) µm, l/w 1–1.1(–1.2) (n = 34), hyaline, verruculose, single-celled, non-septate, sub-globose, oblong or slightly tapered downwards, thick-walled.

Culture characteristics. Optimal growth at 25 °C on all media, poor and limited growth at 30 °C, no growth at 35 °C. Although MEA exhibited good growth, precultures were made on it.

On MEA and PDA, growth is slow, colony is creamy white, finely farinose by scant effuse conidiation; on PDA, reverse brownish, surface turning greenish-brown. On MEA at 25 °C after five days colony radius 5–7 mm; colony circular, dense, thick, first whitish, becoming zonate after a few weeks, turning olive-green to brown with yellow-greenish, farinose center; conidiation effuse, on short odd

verticillium like conidiophores. On SNA colony radius at 25 °C after 2 weeks 6–9 mm; colony dense, hyaline, turning greenish or olivaceous from conidia. Conidiation following growth, effuse, on aerial hyphae and short odd verticillium-like conidiophores, spreading from the plug. ***Conidiophores*** simple, 1–4 level, are branched and tapered at the tips, bearing few asymmetric side branches, terminated by solitary phialides of 2–3 divergent phialides. ***Phialides*** (5.5–)7–10(–14) × (1.6–)2.5–2.9(–3.5) µm (n = 32), mostly gregarious, lageniform, less commonly subfusiform, not thickest near the base. ***Conidia*** (2.8–)3.1–3.7(–4) × (1.7–)2.2–2.7(–3.2) µm (n = 70), variable shape and size, typically oblong and pale yellowish green when fully mature, oval, ellipsoid and hyaline when immature, straight or slightly curved, sides sometimes pinched, smooth; base often truncate.

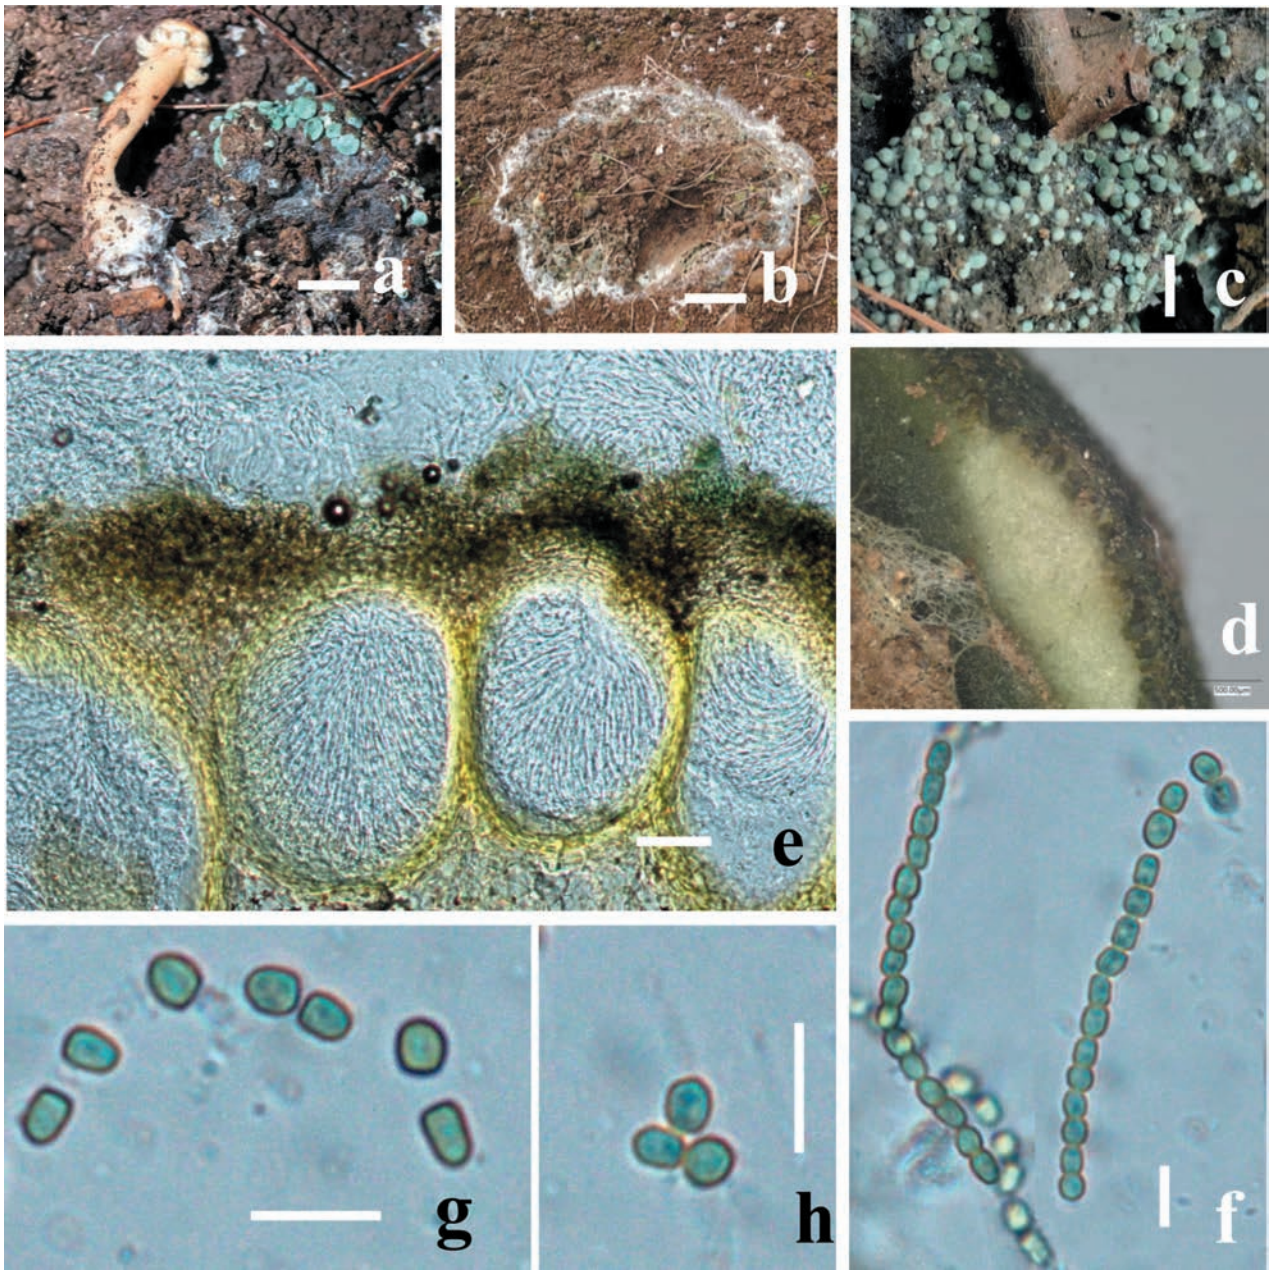

Figure 5. Morphology of *Trichoderma viridistromatis* (HGUP 24-0004, GUCC 24-0005) **a, b** diseased in the field, **c** fresh stromata on natural substrate **d** cortical and subcortical tissues **e** ascomatal tissue in section **f** asci with ascospores **g, h** ascospores. Scale bars: 10 mm (**a–c**); 1,000 µm (**d**); 50 µm (**e**); 20 µm (**f–h**).

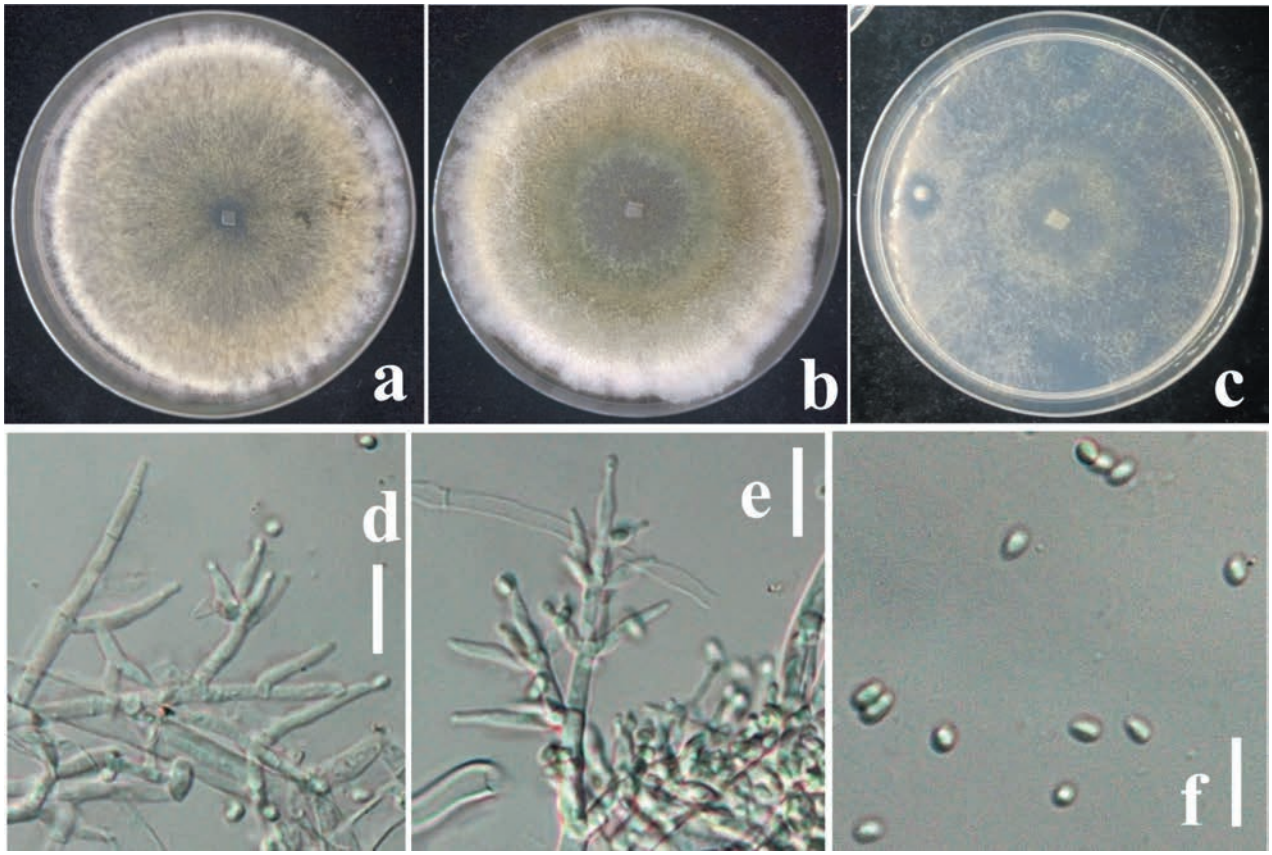

Figure 6. a cultures on MEA (five days) **b** cultures on PDA (five days) **c** cultures on SNA (four days) **d** conidiophores **e** phialides **f** conidia. Scale bars: 10 µm (**d, e**); 5 µm (**f**).

Habitat. On mushroom cultivated field, associated with *Stropharia rugosoannulata*.

Distribution. China, Guizhou Province, Guiyang City, and Liupanshui City; Guizhou City in Anshun Province.

Material examined. China • Guizhou, Liupanshui City, Shuicheng District, 24°55'39.936"N, 121°11'30.264"E, on soil surfaces of *Stropharia rugosoannulata* cultivated field, 16-November-2023, E. Tarafder and F.H. Tian (HGUP 24-0004, holotype); ex-type living cultures GUCC TB1120, GUCC TB1121 and GUCC TB1122.

GenBank accession numbers. GUCC TB1120 (ITS: PP922277; *rpb2*: PP954944; *tef1-α*: PP954950); GUCC TB1121 (ITS: PP926290; *rpb2*: PP954945; *tef1-α*: PP954951); GUCC TB1122 (ITS: PP922285; *rpb2*: PP954946; *tef1-α*: PP954952)

Notes. Morphologically, our newly described taxon *Trichoderma viridistromatis* shares common characteristics with *T. aerugineum* (CBS120541) and *T. britannicum*, a species previously isolated from dead stems and leaves of *Calamagrostis epigejos*. However, *T. viridistromatis* differs from *T. aerugineum* by having smaller stromata (0.5–2 mm in diameter, compared to ca. 1 mm thick in *T. aerugineum*) and larger phialides (7–23 × 2.4–4 µm in *T.* aerugineum) and ascospores (8–12 × 4–6 µm; Table 4) (Chaverri and Samuels 2004). Additionally, it can be distinguished from *T. stropharіensis* by its larger stromata (1–14 mm in diameter, 1–11 mm thick in *T. stropharіensis*) and significantly larger subglobose to elongated ascospores (8.4–16.9 × 5.5–8.1 µm).

Table 4. Morphological comparison of *Trichoderma britannicum*, *T. aerugineum*, *T. viridistromatis*, *T. spinulosum*, and *T. strophariensis*.

Taxon (holotype)	Ascospores	Conidia	Substratum	References
T. britannicum	10–16 × 4.5–6.2 µm	4.7–19.3 × 4–6.2 µm	Decaying wood of broadleaf trees	Jaklitsch et al. 2014
T. aerugineum	8–12 × 4–6 µm	3–5 × 2–4 µm	Decaying wood	Chaverri and Samuels (2004)
T. viridistromatis	**3.4–5.6 × 2.4–3.3 µm**	**2.8–4 × 1.7–3.2 µm**	**mushroom species (*Stropharia*)**	**This study**
T. spinulosum	5–7 × 3–4 µm	3.5–4.7 × 3–3.7 µm	On stems of *Chelidonium majus*	Jaklitsch and Voglmayr 2015
T. strophariensis	8.4–16.9 × 5.5–8.1 µm	8.5–25.5 × 5.7–17.9 µm	mushroom species (*Stropharia*)	This study

In comparison, *T. britannicum* has discoid, convex to turbinate stromata surrounded by light brown radial mycelium and much larger one-celled ascospores (10–16 × 4.5–6.2 µm; Table 4) (Jaklitsch et al. 2014). The phylogenetic positions of the new taxon (Fig. 2) demonstrated that *Trichoderma viridistromatis* is closely related to *T. strophariensis*, *T. britannicum*, and *T. aerugineum*, with strong statistical support (Fig. 2). However, our isolate differs from *T. britannicum* with 3% (17/610 nucleotides, with five gaps) in ITS region, 2% (20/1080 nucleotides, no gaps) in *rpb2* gene, and 4% (55/1244 nucleotides, twenty-one gaps) in *tef1-α* gene. Moreover, the difference in our collections with *T. aerugineum* is more than 2% (10/610 nucleotides, ten gaps) in the ITS region, 7% (79/1080 nucleotides, no gaps) in the *rpb2* gene, and 6% (78/1244 nucleotides, eleven gaps) in *tef1-α* gene (Table 2). Additionally, the differences between our isolate with *T. strophariensis* are 4% (29/610 nucleotides, four gaps) in ITS region, 4% (46/1080 nucleotides, no gaps) differences in *rpb2* gene, and 5% (65/1244 nucleotides, twenty-five gaps) differences in *tef1-α* gene also supported *T. viridistromatis* to be a distinct species compared to *T. strophariensis* and *T. britannicum* respectively.

Discussion

Green mold is a prevalent disease in mushroom cultivation that disrupts the average growth of mushroom fruiting bodies or mycelium and inhibits the average growth of mushrooms (Zeng et al. 2022). The discovery of two new *Trichoderma* species causing green mold disease significantly advances our understanding of fungal pathogens in mushroom cultivation. This finding underscores the urgent need for effective disease management strategies in agriculture. The pathogenicity of HGUP 24-0001 and HGUP 24-0004 on *Stropharia rugosoannulata* was confirmed in controlled field tests, where both strains caused symptoms consistent with green mold disease. The rapid development of green mycelia covering the mushroom trays fulfilled Koch's postulates. In this study, the rapid colonization of mushroom trays by green mycelia is a clear indicator of the aggressive interaction between the pathogens and the host, a situation of intense concern, leading to significant damage to the mushroom fruiting bodies. The occurrence of mold diseases affecting *S. rugosoannulata*, highlights the significant economic losses due to fungal infections in mushroom cultivation (Huang et al. 2023). The infection rate of both isolates in the mushroom trays mirrors their incidence in the field, indicating a potentially

significant agricultural impact. A detailed observation of symptoms, from initial mycelial growth to full substrate colonization, provides a comprehensive timeline of disease progression and is crucial for effective disease management in mushroom cultivation (Zhang et al. 2022).

Morphological analysis of the newly identified *Trichoderma* species revealed distinct characteristics. The typical symptoms of green mold disease were greenish mycelial growth and rotting of the fruiting bodies of the mushrooms. Moreover, molecular phylogenetic analyses of the nuclear ribosomal internal transcribed spacer (nrITS) region, the second largest subunit of RNA polymerase II (*rpb2*), the partial translation elongation factor 1-alpha (*tef1-α*) provided conclusive evidence for the delineation of the two new *Trichoderma* species, and these isolates were separated from previously identified and described species of *T. britannicum*, *T. aerugineum*, *T. danicum*, and *T. spinulosum* and properly placed within the distinct clades (Fig. 2). This molecular approach not only confirmed the novelty of the species but also highlighted the genetic diversity within the genus *Trichoderma*. This study successfully identified and described two new species of *T. strophariensis* and *T. viridistromatis* as the causal agents of green mold disease in *Stropharia rugosoannulata* in Guizhou Province, China.

The discovery of these new pathogens emphasizes the need for continuous monitoring and research on fungal diseases affecting economically important mushrooms. Integrating morphological and molecular identification techniques provides a robust framework for identifying and characterizing new fungal pathogens, ultimately improving disease management practices. Future studies should continue to explore the agricultural and biotechnological potential of these and other *Trichoderma* species, contributing to a deeper understanding and sustainable management of fungal pathogens in agriculture. This new pathogen can infect the mycelia of *S. rugosoannulata* at an early stage and the entire fruit body at maturity, making it a challenging competitor in the field. However, our significant findings also reveal an unexpected diversity of *Trichoderma* in China, highlighting the need for further research and inspiring future investigations.
